At all events, the subject is worth occasional revival, if only as a reminder to the younger men that there are some remedies of the past age which are worthy of their attention and renewed examination.

— The Boston Board of Health is now publishing a monthly statement of the mortality of the city.

# MASSACHUSETTS GENERAL HOSPITAL AND OUT-PATIENT ABUSE.

EVERY ONE in New England interested in medicine takes an interest in the Massachusetts General Hospital. To many its Annual Reports bring reminiscences of pleasant student days when the professional cares and anxieties were only potential, or were borne for the most part by broader shoulders than their own. Of the many who read the annual report with pleasure we venture to say, that the great majority will turn, this year, to the portions that relate to the experiment, now going on, in regard to the restriction of the Out-patient service to the really needy.

Our readers will doubtless recall the paper, published in the JOURNAL something over a year ago, on Out-patient Abuse, by Dr. Whittemore, Resident Physician and Superintendent of the hospital, in which he proposed a remedy for the crowding of the Out-patient Department. This paper was incorporated in the report of last year. The plan was adopted by the trustees, and for the past nine months has been in operation. The time is as yet too short to judge fairly of its merits, and the scheme seems to be regarded by the authorities as on trial simply. We therefore allow the report to speak for itself: —

"The Trustees have continued their efforts to restrict the service in the Out-patient Department to the class of suffering poor whom the hospital was founded to relieve. The practice of exacting a nominal fee from all applicants save the very poor was discontinued early in the year, as it was found not to accomplish the good it was intended to effect, and to be productive of positive ill results. In April an experienced person was appointed to examine all applicants, in order to ascertain whether their circumstances entitled them to the benefits of a gratuitous charity. The results of his investigations will be found embodied in the report of the Resident Physician. It will be seen that, of 1,250 cases visited at the addresses given, 545 were pronounced undeserving of charitable aid. It is no doubt true that, to a large number of these, the term impostor would be a harsh and unjust one to apply. It may well be feared that the past practice of the hospital and of similar institutions has tended to disseminate the belief that whatever the means of the sufferer, sickness entitles him to free advice and treatment. The managers of such institutions in this country and in Europe are now fully awakened to the dangerous influence of such a belief in its tendency to impair the spirit of providence and self-dependence so essential to good citizenship. The aim of such an investigation of cases as that now in force in our Out-patient Department should be rather to prevent than to detect improper applications for treatment. It is probable that the result will be to diminish in some degree the number of those annually treated, but it is well to remember, that to judge of the success of an institution by the number of its patients is to apply the easiest but not the most adequate test. The Trustees feel it to be their duty to check, so far as they may, the further spread of a tendency which they believe

already to have assumed the proportions of a great evil."

The report of the Resident Physician reads as follows:—

"Acting upon instructions received from the Board of Trustees, I employed, on the 1st of April, a competent and experienced man to investigate the condition of every person who applied for admission to the Out-patient Department for treatment, and with the following results:—

|  |        |
|--|--------|
| Number of applications for admission . . . . . | 10,612 |
| Number admitted . . . . .                      | 9,220  |
| Number refused . . . . .                       | 1,392  |
| Number of visits of investigation . . . . .    | 1,250  |
| Number found deserving of charity . . . . .    | 705    |
| Number found undeserving of charity . . . . .  | 545    |
| Number sent to physicians' offices . . . . .   | 791    |

"The greatest consideration for all applicants has been exercised, and no one excluded who did not themselves give sufficient proof that they were not objects of charity."

In addition we are given the total number of new patients in the Out-patient Department, namely, 18,443, a decrease from last year of 2123.

We had hoped for some statement as to the value of the method in the eyes of those who have watched its workings, and we still hope such a statement will be given when a full year has elapsed. Meanwhile our interest in the subject has led us to inquire how the method has affected various classes.

The following table, the figures being taken from the printed reports of the two years, shows some interesting particulars.

| OUT-PATIENTS.   | 1881.  |        | Percent-<br>Increase. |
|---|--------|--------|-----------------------|
|   | 1881.  | 1880.  |                       |
| Number of new patients . . . . .                        | 18,443 | 20,566 | 10+                   |
| Men . . . . .   | 6,745  | 7,809  | 14—                   |
| Women . . . . .   | 7,770  | 8,568  | 10—                   |
| Children . . . . .                                      | 3,968  | 4,189  | 05+                   |
| Americans . . . . .                                     | 10,128 | 12,328 | 18—                   |
| Foreigners . . . . .                                    | 8,315  | 8,138  |                       |
| Residents of Boston . . . . .                           | 12,088 | 13,519 | 11                    |
| Of other places . . . . .                               | 6,325  | 7,059  | 09                    |
| Medical department for women . . . . .                  | 3,462  | 3,971  | 12                    |
| Medical department for men and children . . . . .       | 3,454  | 4,181  | 17                    |
| Surgical department . . . . .                           | 4,559  | 4,590  | 03                    |
| Ophthalmic department . . . . .                         | 402    | 404    | 04                    |
| Dental department . . . . .                             | 4,018  | 4,217  | 04                    |
| Department for diseases of the skin . . . . .           | 1,082  | 1,339  | 18                    |
| Department for diseases of the nervous system . . . . . | 420    | 453    | 08                    |
| Department for diseases of the throat . . . . .         | 993    | 1,199  | 24+                   |
| Total attendance . . . . .                              | 35,136 | 37,215 |                       |
| Average daily attendance . . . . .                      | 114    | 120    |                       |

\* Increase .02.

This table presents matters somewhat more vividly than a plain statement of facts, and if we may trust the figures the comparison brings out some interesting points.

The decrease is greatest among men, occurs in the same proportion as the general decrease, among the women, and is least among children; it is manifest in the medical department rather than in the surgical, while the greatest diminution takes place in the special departments for diseases of the throat and skin. Exceedingly interesting is the fact that the entire decrease has taken place among the native born re-

cipients of the charity while a slight increase is noted among the foreigners.

A question yet to be settled remains, as to whether the falling off in the attendance at this one charity will be followed by a proportionate increase in the other charities.

#### MEDICAL NOTES.

—The Committee on Public Health of the Massachusetts Legislature have reported the following act for the preservation of the health of females employed in manufacturing, mechanical, and mercantile establishments:—

"Section 1. Every person or corporation employing females in any manufacturing, mechanical, or mercantile establishment in this Commonwealth, shall provide suitable seats for the use of the females so employed, and shall permit the use of such seats by them when they are not necessarily engaged in the active duties for which they are employed, to such an extent as may be reasonable for the preservation of their health.

"Section 2. A person or corporation violating any of the provisions of this act shall be punished by a fine of not less than ten dollars nor more than thirty dollars for each offense."

—A colored physician has been appointed an assistant in the Central Lunatic Asylum for colored people in Richmond, Virginia. The designation was made by a board of directors appointed by the governor, and this assignment by State authorities to a public institution is an event worthy of special comment. For the first time in Virginia, a colored man is now to fill a prominent office. The doctor is a graduate of a Western medical college.

—Dr. Dolan (*Medical Press and Circular*, May 18, 1881) comes to the following conclusions respecting venesection: (1) venesection has no direct influence over external or internal inflammation; (2) it is useless in external inflammations; (3) it is useful in those external inflammations which affect the cardiac and respiratory functions; (4) local bleeding has a potent, useful effect in external inflammations; (5) local bleeding, in cases of internal inflammation in which a direct capillary circulation exists between the skin and the part affected, is of decided benefit; (6) the value of local bleeding when these indications are not present is doubtful.

—According to the present arrangement the students at the Boston Dental College attend lectures during the first year as follows: on Inorganic Chemistry, Physiology, Therapeutics and Materia Medica, Operative, Clinical and Mechanical Dentistry; they must also pass a written examination in the first three chairs.

In the second year they attend lectures on Surgery, Organic Chemistry, Anatomy, Pathology, Microscopy and Dental Histology, Operative, Clinical, and Mechanical Dentistry, and pass written examinations in all these branches.

The working of this new régime is said to have been most satisfactory to professors and students.

—A case of very low temperature following exposure to cold during drunkenness is reported by De Gastel in *La France Medicale*. The temperature in the rectum was 26.5° C., about 79° F., when taken about six hours before death. The autopsy revealed the fatty degeneration of the tissues usual in alcoholism, but no lesions in themselves fatal. Dr. F. C. Shattuck reported a case brought into Traube's ward in the hospital in Berlin, under similar conditions, with a temperature of 76° F., which recovered.

#### NEW YORK.

—The forty-first annual commencement of the University Medical School was held at the Academy of Music on the evening of March 7th, when diplomas were conferred upon two hundred and thirteen graduates, and the usual prizes were awarded. The class valedictorian was John Culver Beckman, and the address to the graduates was made by the Rev. Dr. Richard S. Storrs, of Brooklyn. There being no chancellor of the University at present, Dr. John Hall having declined the position (which was offered him after the resignation of Dr. Howard Crosby), Prof. Alfred C. Post, of the medical department, discharged the chancellor's functions on this occasion.

—The commencement exercises of the Bellevue College came off at Chickering Hall on the 16th. Dr. James W. McKean delivered the valedictory, and Dr. J. S. Billings, of Washington, the address to the graduates. There were one hundred and sixty-three in the class. The alumni of the college had their annual dinner at Delmonico's in the evening, and Dr. Billings was among the guests present.

—At the last meeting of the Academy of Medicine, March 16th, Dr. H. G. Piffard exhibited a medical battery designed by Dr. L. P. Felton, after which came a paper by Dr. Frank H. Hamilton, entitled, *The Struggle for Life against Civilization and Aesthetics*, which had been prepared as a supplement to the recent discussion on plumbing and sanitation before the Academy. As Dr. Hamilton was indisposed, the paper was read by Dr. Edward Bermingham. After reviewing the points brought out in the previous discussion, the writer of the paper arrived at the conclusion that none of the remedies for existing evils which had been suggested by the various speakers were altogether satisfactory. Sanitary science, he believed, had not kept pace with the advance of civilization, the term civilization being used in its broad and legitimate sense as including not only mental culture, with progress in science and art, but also the comforts, luxuries, and aesthetics of life, which were its natural and inevitable concomitants. If certain of the latter elements of civilization could not be dispensed with, it would be found impossible, he feared, to contend successfully with many of the diseases which now contributed so largely to the increase of the mortality rates.

The means employed to light and warm (or, as was often and more correctly said, to "heat") our houses having already deprived us of a large propor-

tion of our oxygen, Dr. Hamilton went on to say, the plumbers had at last rendered actually poisonous what remained by connecting the interior of almost every room in our dwellings with the sewers. Possibly nothing would so forcibly illustrate the magnitude of the evil under consideration as the fact that it had given birth to a new profession, that of the sanitary engineer. Up to the present time, however, the sanitary engineers had only succeeded in mitigating the evils they had been asked to remove, and in some notable instances had not even accomplished as much as this. It had been shown conclusively that, no matter how perfect the system of plumbing was, the water in the traps of sewerage pipes would sometimes be syphoned out and sometimes evaporated, and, except where there was a constant flow of water, was always foul. The ventilation of soil pipes by air openings into the street and to the roof was of great value, but it was not invariably a protection. In New York the foul gases were largely due to an imperfect street sewerage system, and these gases he believed to be the most frequent cause of diphtheria, typhoid fever, and other zymotic diseases. It was now so well recognized that all known means of protection against these deadly gases sometimes failed, that a number of wealthy gentlemen who were now building residences had had all pipes connecting with the water and sewer systems put in annexes, and he was convinced that the only solution of the house sanitation question was to keep all such pipes out of the dwelling apartments. In the removing of the unwholesome atmosphere of our houses the concessions demanded were summed up as follows: First, that all plumbing having a direct or indirect communication with the sewers should be excluded from those portions which were habitually occupied. Second, that we should return to the open fire or the grate as a means of warming our private houses. Third, a diminished consumption of oxygen by gas burners. The remainder of Dr. Hamilton's paper was devoted to an enumeration of other evils characterized by a disregard for the laws of hygiene, which were incidental to our modern civilization.

Among those who took part in the discussion which followed the reading of the paper were Professor Chandler, President of the Board of Health, Professor Doremus, and Dr. Billings, of Washington. The latter stated that a series of careful experiments had shown that the popular opinion in regard to the amount of gases in sewer pipes was greatly exaggerated, and that he thought it extremely improbable that such gases produced specific diseases, although they no doubt did undermine the health and predispose the system to such diseases.

—The first annual meeting of the New York Medical Mission was held on the 14th of March, at the Broadway Tabernacle. Dr. William H. Thomson, who is its president, in his address stated that city hospitals, as at present conducted, were apt to do as much harm to the moral character of inmates as they conferred benefit upon the body, and that these institutions were to no small extent homes for tramps and an encouragement to vagabondage.

## Miscellany.

## THE CASE OF GUTEAU.

NEW YORK, March 18, 1882.

MR. EDITOR, — The letter relating to the mental state of Charles J. Guiteau, published in your issue of March 9th, contains certain statements conflicting with what I believe are the established facts of the evidence taken during the trial of the assassin. It is stated by the writer that the counsel for the defense resorted to the "trick" of placing the diagrams of the *conformateur* tracing offered in evidence by Dr. W. Kempster, over that obtained by bending a piece of lead pipe around the head, offered in evidence by Dr. McLane Hamilton, and the writer adds that "of course" they did not agree.

On page 1523 of the printed report of the trial, Dr. Kempster is reported, and no doubt substantially correctly, as saying: "There is a very decided difference between the *shape of the skull* of these two — between Nos. 1 and 2. Here these *centres of ossification*, as we call them, are very prominent, very well marked (holding up two other cuts). There, again, are two shapes taken from two heads; one being long and narrow, and the other broad." On the same page the witness repeatedly speaks of his cuts and tracings as representing the "shapes" of heads of certain prominent men. On page 1633, the same witness, submitting papers to the jury, is reported as saying: "You will also find upon one of the charts an outline of the head of the prisoner." Again and again he speaks of this chart as indicating the *shape of the prisoner's head*; and he swore, as Mr. Scoville says (2180), that the diagram he submitted was a correct representation of Guiteau's head. Dr. McLane Hamilton also submitted a diagram, and in order to test the correctness of these alleged representations of the assassin's head, Mr. Scoville laid them over each other. The prosecution, seeing the precarious position in which their medical witnesses, or at least one of them, was being placed, endeavored to prevent Mr. Scoville from making the comparison and from submitting a chart, showing the gross discrepancy (nearly an inch and a half) between the diagrams of Drs. Hamilton and Kempster; but it passed in evidence, and is on record (p. 2176). If he was not justified in applying such accurate tests as the foot-rule and compass to prove that one of the witnesses at least had offered an inaccurate diagram, for the purpose of contradicting my statements, then I agree with Dr. McLane Hamilton that it was a "trick" to venture to test the veracity of a medical witness by the testimony of his partners in the unfortunate transactions at Washington.

It would be easy to demonstrate a very unsymmetrical head to be symmetrical, and *vice versa*, by measuring the head in a certain way. It is still easier to cause slight disparities to disappear by using as thick lines in making the traces as are found in the diagrams on page 236 of the JOURNAL. Unless a large number of traces are taken, measurement by palpation and the artist's eye are far more reliable than contour diagrams. The cast of Guiteau's head, which was admitted to be a correct one, was recently exhibited at a meeting of the New York Medico-Legal Society; its

deformity was unquestioned, and recognized by every one present, yet not one of the traces of Dr. Hamilton is taken in such a way as to show it. With your license, I shall submit to your readers a series of correct outlines taken from this cast, on a future occasion, and then they may judge for themselves on this point, as did the members of the New York Medico-Legal Society, who regretted that notwithstanding the abundant notice given, the experts for the prosecution absented themselves from a meeting where the scientific discussion would have developed their opinions and exhibited the value of the latter under far better auspices than a jury trial.

When Mr. Scoville handed Dr. Kempster the cast, and asked him, on the doctor's stating that it represented a very well-shaped head, to look around the room and show him a single head as much out of proportion as Guiteau's, the witness was silent, not even casting his eyes around; although Mr. Corkhill, of whose head he had obtained a tracing by the *conformateur*, claimed that his was more unsymmetrical than Guiteau's, and he was sitting right in front of him. Was it not considered safe to risk a genuine comparison?

No scientific anthropologist employs the latter's *conformateur* to delineate cranial contours. This instrument, while fulfilling its functions sufficiently well for a tradesman, yields the most ridiculous projections of the skull shape; an example of this is to be found on page 1526, the tracing of Jno. P. Foley, offered in evidence by Dr. Kempster, has the shape of a peanut, and presents the remarkable proportion 100:45; almost the same remarks apply to the tracings of Isaac Johnson, and Colonel Wyman. Dr. Hamilton is under a misapprehension if he believes that brachycephaly and dolichocephaly constitute atyp; a head may be at either extreme and yet be typical. But flattening of either end of the cranial ovoid, ridges and promontory-like extensions of the cranial vault, and marked asymmetry, these are atypical. Guiteau's occiput is flattened (as those of thirteen subjects of *manie raisonnée* described by Campagne), there is a bold jutting out on the left side, and no fair measurement can be taken in a frontal plane two inches behind the ears without showing an unusual degree of asymmetry.

Still, the whole question of the cranial contour is a subsidiary one. He who cannot recognize that Guiteau is insane on the strength of his mental manifestations will naturally fail to appreciate the significance of a cranial anomaly, as well as of other physical signs; while he who does recognize the clinical evidences of a well known form of insanity in the prisoner will not require such collateral support, although the existence of somatic evidences which cannot be shammed, associated, as they are in Guiteau's case, with a specific family history of heredity and degeneration, cannot fail to be a welcome supplementary proof.

I differ from Dr. Folsom in the interpretation of the motor disturbances. Recognizing on the one hand that monomania may be in itself associated with various defects and anomalies of innervation, and on the other that, as in one case under my own observation,<sup>2</sup> and in others described by Hoestermann and Meyner, parietic dementia may complicate monomania,<sup>3</sup> being then of very slow growth and insidious approach, I cannot deny

<sup>2</sup> And another within my knowledge.

<sup>1</sup> Referring to tracings obtained from the heads of various persons by the latter's *conformateur*. Italics mine.

<sup>3</sup> As I have proposed to term the "Originaere" and "Primaere Verrichtheit" of the Germans.

the possibility of its development on the one hand, while I see no positive grounds for anticipating it.

As Dr. McLane Hamilton states that Guiteau, in his opinion, presented no evidences of any known mental disease, I may be permitted to direct the attention of the reader to a few standard works which no one could read without finding as fair counterparts of Guiteau's whole history, nay, even of his crime or attempts at such, as one can expect to find in text-books: Krafft-Ebing, *Lehrbuch*; Schuele, in *Ziemssen's Cyclopædia*; Bucknill and Tuke, *Manual of Psychological Medicine*; Campagne, *Traité de la manie raisonnée*; Dagonet, *maladies mentales*, etc., etc.

I refer to these works, because I do not believe it to be either necessary or allowable for a writer in a medical journal to recapitulate what should be at the fingertips of every one qualified to speak on a subject, and to retail the A B C of Psychological Medicine. Very respectfully yours,  
EDWARD C. SPITZKA.

### ASPIRATION OF THE CHEST.

MR. EDITOR.—I am very desirous of learning whether any well-authenticated case of death *immediately after, and apparently solely dependent on, aspiration of the chest* has occurred in the United States or Canada. May I ask, through you, any one of my professional associates upon this continent to notify me by postal card of such fact, sending the address to which I can write for fuller information.

Respectfully yours, HENRY I. BOWDITCH.  
113 BOYLSTON STREET, BOSTON, MASS.,  
March 13, 1882.

### LETTER FROM ALBANY.—PROPOSAL FOR A HARVARD ALUMNI ASSOCIATION.

MR. EDITOR.—A medical alumnus of Harvard lately went to Commencement, at Cambridge, and found himself, by mere superfluity of numbers, left out in the cold. As he stood and saw the last graduated class file in to dinner in the grand old Memorial Hall he had a kind of lonesome feeling come over him, as if the medical graduate was of not much account to his prolific Alma Mater. To be sure she gives him a sheepskin as an undergraduate,—still, as things now are, Harvard Medical Alumni have, as such, no place assigned by their Alma Mater in the family gathering around the *lures* and *penates*. The only way this alumnus did get in to the dinner was by the courtesy of a personal invitation of one of the corporators after waiting one year. Not so with Union University. She has an Association of her Medical Alumni, nine years old, in full organization, and successful working. The meetings are held in connection with the Medical College Commencement at Albany, and the occasions are of great interest to those concerned.

The meeting to-day was one well attended, well managed, and full of *esprit de corps*.

The proceedings were of course most of them of more interest to the participants than to a looker on; still the report of the prize committee of the alumni was a paper of a high tone and beautiful spirit. It was a complete, graphic digest of the successful and unsuccessful papers submitted, with such kind words

for the writers of the latter as must have soothed their feelings and stimulated them to greater exertion. The McNaughton prize of \$100 was awarded to Dr. James H. Salisbury, of New York, for an original essay on Malaria.

The March Memorial Prize of \$100 on morbus coxarius was awarded to Dr. C. C. J. Schuyler, Troy, N. Y.; the Armsby Memorial Prize to Dr. Clinton B. Herrick, of Troy, N. Y.

The exercises graduating fifty-four students were held at eight, p. m., in Tweddle Hall. The two addresses by the students were on Medical Sociology or ethics from a neophytic standard. We hoped to have heard something in the line of original research from the theses.

The address of Dr. S. O. Vanderpool, LL. D., to the class, was a masterpiece of advice as to the sociological and subjective relations of the class in the future. It was good enough for any professional man. There was a purity of tone, an elevation of taste, in the clear, concise, elegant prose that charmed like a poem. It was decidedly the effort of the occasion, and is something for the graduates to cherish in their memories through life. The practical hints, not given in the published account, were as follows: "Do not sit on the bed of your patient." "Do not talk 'horse' to patients." "Attend to the professional part of your visit; be as deep, kind, thorough, and long as you please; but when through, *leave*." "Don't try to be a 'good fellow,' I am sick and tired of the words." "Never expect to attain professional eminence by being 'hale fellow, well met'." Many physicians socially on good terms with a family lose it professionally, since 'familiarity,' etc." "Don't be politicians, speculators, or anything else but *doctors*. On questions of public health and State medicine interfere ever and always." "Study the physical characters of your locality, and sooner or later your study will bear fruit for the good of all concerned." "If you are of medium capacity and gifted with industry, application, and honesty, you will eclipse more gifted men in your profession."

The speeches of the Alumni dinner at the Delavan were a treat. Solid, substantial, honest, sturdy Dutch *hits* really enlivened the scene, and kept an undivided attention up to 2.30 A. M., March 2d. The usual complimentary tilts between the different professions were admirable, and I must say went ahead in some respects of the remarkable efforts of wit exhibited at the annual dinner of the M. M. S. in Music Hall, Boston. The quiet humor of the Dutch character, stirring up and giving thrusts that tickled but did not sting, was finely brought out here. Though the hour was very late and time to be a-bed, still every speaker had a hearty, respectful hearing, considerate and humoring. I never saw such attention given in Boston to after-dinner talk. I can easily see now how guilds and debating societies flourished in Holland three centuries ago.

Now, why cannot Harvard Medical Alumni have an Association?

It need cost but one dollar a year, and there are plenty of Alumni in Boston to be the executive committee.

To make a beginning, I ask all *Harvard Medical Alumni* who wish to form such an organization to send their names to the Medical Library Rooms, 19 Boylston Place, Boston. When a sufficient number

have signified their interest in the matter it will be possible to call them together and organize duly, if it is so desired.

The example of the Albany Medical College is an excellent one, and nothing but good can follow the

perpetuation of the influence our own noble Alma Mater has had in forming and sustaining a high medical *morale* among her Alumni.

ALUMNUS OF 1856.

ALBANY, March 1, 1882.

REPORTED MORTALITY FOR THE WEEK ENDING MARCH 11, 1882.

| Cities.                           | Population by Census of 1880. | Reported Deaths in each. | Deaths under Five Years. | Percentage of Deaths from       |                |                       |                |            |

Deaths reported 2714 (no reports from St. Louis, New Orleans, and Cleveland): 1116 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 631; consumption 395, lung diseases 415, diphtheria and croup 181, scarlet fever 133, small-pox 74, measles 50, typhoid fever 42, whooping-cough 36, diarrheal diseases 32, cerebro-spinal meningitis 27, erysipelas 24, puerperal fever 17, malarial fevers nine, typhus fever three. From *measles*, New York 31, Chicago eight, Philadelphia and Milwaukee three each, Pittsburgh and Buffalo two each, Brooklyn one. From *typhoid fever*, Philadelphia 14, New York five, Chicago and Boston four each, Baltimore, Cincinnati, Pittsburgh, and Buffalo two each, Milwaukee, Providence, New Haven, Charleston, Nashville, Taunton, and Waltham one each. From *whooping-cough*, New York 20, Pittsburgh four, Brooklyn, and Boston three each, Philadelphia, Chicago, Buffalo, Milwaukee, Salem, and Newton one each. From *diarrheal diseases*, New York 13, Boston four, Cincinnati three, Brooklyn, District of Columbia, and Lowell two each, Chicago, Baltimore, New Haven, Somerville, Holyoke, and Spencer one each. From *cerebro-spinal meningitis*, Buffalo six, New York five, Chicago three, Philadelphia, Baltimore, New Haven, and Worcester two each, Pittsburgh, Milwaukee, Providence, Charleston, and Nashville one each. From *erysipelas*, New York six, Brooklyn and Providence three each, Chicago, Boston, and Baltimore two each, Philadelphia, District of Co-

lumbia, Pittsburgh, Buffalo, Charleston, and Somerville one each. From *puerperal fever*, Buffalo five, New York seven, Boston three each, Baltimore and Milwaukee two each, Chicago and Lowell one each. From *malarial fevers*, New York seven, Chicago and New Haven one each. From *typhus fever*, New York two, Chicago one.

Eighty-six cases of small-pox were reported in Cincinnati, Pittsburgh 44, Baltimore 12, Milwaukee five, and Buffalo one; diphtheria 20 cases, scarlet fever 16, typhoid fever eight in Boston; scarlet fever 22, and diphtheria three, in Milwaukee.

In 36 cities and towns of Massachusetts, with a population of 973,586 (population of the State 1,783,086), the total death-rate for the week was 19.34, against 20.37 and 22.96 for the previous two weeks.

For the week ending February 18th, in 173 German cities and towns, with an estimated population of 8,397,701, the death-rate was 27.8. Deaths reported 4488: under five 2075; pulmonary consumption 648, acute diseases of the respiratory organs 540, croup and diphtheria 233, scarlet fever 99, whooping-cough 72, typhoid fever 53, measles and rotheln 42, puerperal fever 29, typhus fever (Erling two, Thorn, Tilsit, Graudenz, Heilbrunn) six, small-pox (Königsberg, Mulheim two) three. The death-rates ranged from 15.1 in Weisbaden to 50.5 in Dortmund; Königsberg 26.6; Breslau 32.1; Munich 39.5; Dresden 25.9; Berlin 23.7; Leipzig 21.7; Hamburg 50.7; Hanover 28.8; Bremen 22.2; Cologne 33.3; Frankfurt-on-Main 26.6.

In the 28 English towns, with an estimated population of 8,455,320, for the week ending February 25th, the death-rate was 25.4. Deaths reported 4118: acute diseases of the respiratory organs (London) 545, whooping-cough 265, measles 148, scarlet fever 101, fever 57, diarrhoea 33, diphtheria, 22, small-pox (London eight) 13. The death-rates ranged from 16.2 in Cardiff to 40.5 in Brighton; Leeds 22.3; Birmingham 23.7; Bristol 23.3; Sheffield 26; Liverpool 25.1; London 26; Manchester 27. In Edinburgh 21.8; Glasgow 24.8; Dublin 33.6.

For the week ending February 25th in the Swiss towns, population 479,934, there were 59 deaths from acute diseases of the respiratory organs, pulmonary consumption 33, diphtheria and croup 16, typhoid fever four, peritonsillar fever three, measles and scarlet fever each two. The death-rates were, Geneva 30.1; Zurich 33.0; Basle 13; Berne 37.9.

The meteorological record for the week ending March 11th, in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the U. S. Signal Corps:—

| Date.            |    | Barom-eter. | Thermom-eter. |       |          |          | Relative Humidity. |            |             |       | Direction of Wind. |            |             | Velocity of Wind. |            |             | State of Weather. <sup>1</sup> |            |             | Rainfall.             |                   |

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MARCH 11, 1882, TO MARCH 17, 1882.

BROWN, H. E., major and surgeon. Having reported at these headquarters, will proceed to Jackson Barracks, La., and report to the commanding officer for duty. S. O. 32, Department of the South, March 14, 1882.

PORTER, JOSEPH Y., major and surgeon. Granted leave of absence for one month, with permission to apply for an extension of one month. S. O. 32, C. S., Department of the South.

The following-named officers of the Medical Department will report in person to the President of the Medical Examining Board, in session in New York City, for examination for promotion, and on its conclusion return to their stations:—

Captain WILLIAM H. KING, assistant surgeon, Fort McHenry, Md., Captain H. S. TERRELL, assistant surgeon, Madison Barracks, N. Y., Captain O. REED, assistant surgeon, Washington Barracks, D. C., Captain H. S. KILBOURNE, assistant surgeon, Fort Porter, N. Y., Captain M. W. WOOD, assistant surgeon, Fort Brady, Mich., Captain R. W. SHUFELDT, assistant surgeon, Washington, D. C., Captain H. O. PERLEY, assistant surgeon, Fort Columbus, New York Harbor, Captain H. G. BRISTON, assistant surgeon, Fort Hamilton, New York Harbor, Captain L. M. MAYES, assistant surgeon, at expiration of his present leave of absence, and then to return to his proper station, David's Island, N. Y.

Captains WILLIAM H. CORNELLER and WILLIAM B. DAVIS, assistant surgeons, at the expiration of their present leave of absence, and upon conclusion of their examination, to report by letter to the Surgeon-General. S. O. 58, A. G. O., March 13, 1882.

#### APPOINTMENTS.

MASSACHUSETTS GENERAL HOSPITAL.—Dr. John Hennessey, Senior Surgeon to Out-Patients, has been appointed Visiting Surgeon, to fill a vacancy caused by the resignation of Dr. Samuel Cabot.

Drs. Maurice H. Richardson and G. W. West have been appointed Surgeons to Out-Patients.

HARVARD MEDICAL SCHOOL.—Dr. William L. Richardson has been appointed Assistant Professor in Obstetrics.

Drs. Charles B. Porter and John Collins Warren have been appointed Assistant Professors of Surgery.

THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT will meet March 27th, at 7.45 P. M. in the Medical Library. Dr.

Porter will report some cases of Popliteal Aneurism, and there will be a discussion on the Surgical Treatment of Aneurism.

BOOKS AND PAMPHLETS RECEIVED.—Stretching of the Facial Nerve for the Relief of Spasm of the Facial Muscles. By W. Allen Sturge, M. D., and Rickman J. Godlee, M. S. (Reprinted from the *Clinical Society's Transactions*, Vol. XIV.)

Eleventh Annual Report of the Board of Directors of the Children's Hospital of the District of Columbia, W Street, between 12th and 13th Streets, N. W.

The Trance State in Inebriety; its Medico-Legal Relations. By T. D. Crothers, M. D., Superintendent Walnut Lodge, Hartford, Conn., with an Introduction on the Nature and Character of the Trance State, by George M. Beard, M. D. A Paper read before the New York Medico-Legal Society.

Notes of Hospital Practice. Part I. Philadelphia Hospitals. Edited by Samuel M. Miller, M. D. Philadelphia, Pa.: Samuel M. Miller, Publisher. 1882.

Reports of the Trustees and Superintendent of the Butler Hospital for the Insane, presented to the Corporation at their Annual Meeting, January 25, 1882. Providence: Angell & Co. 1882.

Serofula and its Gland Diseases. An Introduction to the General Pathology of Serofula, with an Account of the Histology, Diagnosis, and Treatment of its Glandular Affections. By Frederick Treves, F. R. C. S. Eng. London: Smith, Elder & Co. 1882.

Croupous Pneumonia: Is It a Zymotic Disease. By D. W. Prentiss, A. M., M. D. (Extract from *Transactions of the American Medical Association*, 1881.)

The Use of Constitutional Remedies in the Treatment of Ear Diseases. By Samuel Theobald, M. D. (Reprint.)

Case of Obliteration of the Portal Vein (Pylephlebitis Adhesiva). By William Osler, M. D., M. R. C. P. Lond. (Reprint.)

On Some Points in the Etiology and Pathology of Ulcerative Endocarditis. By William Osler, M. D., Montreal. (International Medical Congress.)

On the Brains of Criminals. By William Osler, M. D., Montreal. (Reprint.)

On Cancer of the Breast. With Colored Illustrations. By Thomas William Nunn, F. R. C. S., England, Consulting Surgeon to the Middlesex Hospital. London: J. & A. Churchill. 1882.

Twenty-Ninth Annual Report of the Pennsylvania Training School for Feeble-Minded Children, Elwyn, Delaware County, Pennsylvania. 1882.

Roosevelt Hospital, New York. Tenth Annual Report, from January 1, 1881, to December 31, 1881.

## Original Articles.

A CASE OF FUNGOSITIES OF THE BLADDER CURED BY SCRAPING WITH THE FINGER; WITH SOME REFERENCES TO THE LITERATURE OF THIS AFFECTION.<sup>1</sup>

BY WALTER F. ATLEE, M. D., PHILADELPHIA.

This case is reported because it is a rare one, because it is instructive in a practical point of view, and because consultation with most of his works of reference would not assist the surgeon in benefiting a similar case as much as can be done by following the course pursued here.

Miss S. B. consulted me in the summer of 1880, on account of painful and frequent micturition, with hæmaturia. She was born in April, 1861; her father is a large, strong, and healthy man; her mother died when she was a child, after having suffered from many manifestations of scrofula.

She said she remembered to have felt, occasionally, a slight pain in passing urine, from her earliest recollection. When seventeen years of age she first suffered severely; her urine was then very light in color, with no sediment, but with a strong odor. The pain was while passing the urine and after it had passed; after the emptying of the bladder there was a constant desire to pass something more. She became thin, pale, and haggard. When eighteen years of age some pus appeared in the urine, and occasionally a little blood. These symptoms increased to such an extent that she was obliged to keep her bed for several months. This rest, aided, perhaps, by medical treatment, for she had always enjoyed the care and attention of our most experienced physicians and nurses, made some improvement in her condition, so that she was able again to go out. All the worst symptoms, however, soon returned, and when I saw her, in September, 1880, her state was a very serious one; there was constant inclination to empty the bladder, which could not be resisted oftentimes for more than a half hour, and the loss of blood was considerable.

The urine, when examined at this time, showed pyoid bodies, epithelium from the bladder, and crystals of triple phosphate, together with blood corpuscles in abundance. The blood was of a bright-red color, showing that the urine had not had time to produce those changes in color always produced by long contact with the hæmoglobin of the corpuscles.

With such symptoms, this case seemed clearly to be one of foreign body in the bladder, and the advice given was to attempt its removal without delay. For this purpose the patient was put under the influence of anesthetics, and the urethra was dilated by means of a pair of ordinary dressing forceps, introduced, opened, and withdrawn as often as necessary — this being, in my experience, the best way of effecting this dilatation.

When the finger was then passed into the bladder nothing abnormal was felt, no calculus nor distinct tumors, except that about the fundus were a number of fungosities or soft growths, some of them more than a half inch in length, and about one line in thickness. These were carefully scraped off by the end of the finger and by the finger-nail. This simple operation resulted in the perfect cure of my patient, and until the present time there has been no symptom of a return of her disease.

I call the growths thus removed fungosities, and not villous growths, inasmuch as that they were not like tufts of fine hair (*trilli*), but resembled rather *fungi*, or certain mosses. I have several times seen similar growths removed from the cavity of the uterus, in cases where for years they had been the cause of alarming hæmorrhage. They have, anatomically, the same fundamental structure as the mucous membrane whence they spring; they are simple excrescences of this membrane; they are formed of granular amorphous matter, of cellular tissue in small quantity, and of fibro-plastic elements; almost all have a large number of capillary vessels ramifying through them, and some are covered by epithelium. This epithelium is on the surface, *homologous*, and not *within* the subjacent connective tissue, *heterologous*, which is characteristic of epitheliomatous growths.

I said that one reason for reporting this case to the College was that consultation with most of his works of reference would not enable the surgeon to benefit his patient as much as was done in this case. In Holmes's System of Surgery it is said: "The indications are to allay pain, to subdue spasmodic action of the bladder, to prevent hæmorrhage by internal remedies, and to counteract its effects on the system by chalybeates and nutritious diet. Astringent injections very carefully introduced into the bladder, such as weak solutions of acetate of lead or of nitrate of silver, may be tried; they are, however, not to be repeated more than once or twice, unless marked benefit is observed, and signs of vesical irritation have not been produced by their employment." This is the advice given in almost all surgical works, not only general but special. Even in Coulson's excellent work on Diseases of the Bladder and Prostate Gland, of which a sixth edition was published in 1881, we find nothing but a similar plan of treatment recommended. Though quite out of place, I will cite here the diagnostic symptoms given in Coulson's work between villous growths and calculi as being the best and clearest I have ever met with. In all works the diagnosis of these growths is said to be extremely difficult; for example, in the Dictionnaire de Médecine it is said, "Fungus of the bladder may be suspected, but a precise diagnosis cannot be established."<sup>2</sup> "The pain in calculus is most severe after the urine has been passed, but in villous tumors the discomfort is aggravated by fullness of the bladder, and relieved by its evacuation. The pain in calculus is relieved by rest, which has little or no effect upon the symptoms of tumors of the bladder. The hæmorrhage also in the latter affection is neither decidedly aggravated by movement nor relieved by rest. In villous growths, the blood is generally pure; in hæmaturia, due to calculus, there is generally more or less pus mixed with the blood. Examination by the rectum, or with a sound in the bladder, causes pain in cases of villous growth, and increases the hæmaturia, whereas the symptoms of calculus are not necessarily aggravated by these manipulations."<sup>3</sup>

To return to treatment, Nélaton says: "In women it is sometimes possible to reach the fungus by dilating the urethra and the neck of the bladder. The case of Warner tying a polypus of the bladder in this way is recorded above, and in case of a fungous growth, an analogous operation should be done."<sup>4</sup>

<sup>1</sup> From advance sheets of the Transactions of the College of Physicians of Philadelphia. Read March 1, 1882.

<sup>2</sup> Tome xxx., page 744.

<sup>3</sup> Pathologic Chirurgicale, tome v., page 301.

In Warner's case, above referred to, a polypus penetrated into the urethra of a young woman, and pushed out of the meatus. An incision was made, dividing the half of the urethra, the rest was dilated, and also the neck of the bladder, the tumor was drawn out, and a ligature applied to the pedicle.

In the Principles and Practice of Surgery of Professor Agnew, and in the third edition of Professor Gross's treatise on Diseases of the Urinary Bladder, revised by Dr. Samuel W. Gross, we are advised when symptoms of papillary and polypoid fibromas are seen in women to dilate the urethra by special instruments, and remove them as may be found best under the circumstances of the case. Some eighteen cases altogether are recorded in these works where vesical growths were removed by various operations. Of the prognosis in such cases, Dr. Gross forcibly and truly says: "It is of the worst possible description. Death almost invariably follows from sheer loss of blood or the combined effects of hæmorrhage and pain." Of the treatment, he says, "Surgical interference is demanded imperatively, since without it a fatal issue is almost the inevitable result."

The best account I have met with of the flocculent excrescences or fungosities in the bladder is contained in the Lectures on the Surgical Disorders of the Urinary Organs, by Reginald Harrison, second edition, London and Liverpool, 1880. Mr. Harrison refers to the paper of Robert S. Hudson, in the *Dublin Journal of the Medical Sciences* for June, 1879, to that of Prof. G. Murray Humphrey in the *Medico-Chirurgical Transactions* for 1879, which contains probably the best account to be found of the pathology of growths into the bladder, to Mr. Norton's cases in volume xii. of the *Clinical Society's Transactions*, and to a paper of J. H. Roberts and C. De Morgan in volume xxi. of the *Transactions of the Pathological Society*, where the microscopical appearances are very beautifully represented. He also relates a case (page 359) communicated to him by a Dr. Alexander, where chloroform was given, and the urethra dilated; a wire *Crasen* was passed, and a large growth was removed; smaller growths were removed by the finger. Fifteen months afterwards it was necessary to remove some more by the finger, after which the patient remained well.

This case of Dr. Alexander is doubtless the same as that related in great detail in the *London Lancet* for August 17, 1878. The writer says he cannot find any other case recorded of removal of a villous growth from the female bladder, and quotes from *Virgini's Surgery* "that there is no cure for this affection; the surgeon can only relieve symptoms. The disease usually destroys life in about two years."

Enough has been said to show that cases such as I here report are rare; that they cause great suffering, and, eventually, loss of life, that the means usually recommended fail in giving relief, and that an operation, easily performed, attended by no risk, and followed by no bad consequences, does cure such cases, and that this operation appears to be very generally unknown.

One more observation may be permitted, indeed, seems called for, in this rather desultory paper. This is, that the history of a case such as is here related justifies us in looking favorably upon the resort to a similar proceeding in cases of similar disease in the male patient. An incision into the neck of the bladder, when so much suffering and so great danger to life

are present, is surely justifiable. It is a matter of neither great difficulty nor danger. Even if it was found, after the making of this opening, that the diseased tissues could not be taken away, the patient would, in all likelihood, obtain some relief, from the free passage afforded to the purulent and bloody discharges. There is a case recorded<sup>1</sup> where Billroth did this, and encountering a fibrous tumor, the size of which was such that it could not be extracted through the perinæum, he cut through the recti muscles above the pubic bone, made a transverse incision into the bladder, and then tore through the tumor near its base with the finger, and dissected out the pedicle; the patient was perfectly cured.

## THE MENTAL STATUS OF GUTEAU, THE ASSASSIN OF PRESIDENT GARFIELD.<sup>2</sup>

BY WALTER CHANNING, M. D.

THE question of the mental condition of Guitau on the 2d of July last, when he murdered President Garfield, is one that requires concentration of mind, and freedom from the common sentiments of humanity, to discuss with perfect impartiality. There is an unconscious tendency in the mind to be influenced by a sense of what is right, which may at times mislead well-meaning and truthful men. Connected with this sense of the eternal fitness of things, still further, is a desire to punish wrong or make the guilty suffer for their crimes, and this feeling also distorts and perverts a sound judgment. Perhaps there has been no instance in the civilized world, where, combined with such universal sympathy for the victim, there has been so little feeling for the doer of the foul deed as in this.

It would seem as if every voice in the country had been lifted up in execration against the miserable Guitau, and had made us blind to the ordinary dictates of humanity and dumb to the voice of reason. As a consequence we have been over nice in our discriminations between this point and that, and have thrown aside any testimony possessing the smallest evidence of doubt. In an ordinary case doubt would tell in favor of the prisoner, — in this case it has told against him.

The verdict shows how uncertain the boundaries are to the disease called insanity. In a case where the symptoms are at all obscure we can almost make ourselves believe anything that we choose to. The theory of insanity has seemed to most intelligent persons with whom I have talked, the easiest and most natural way of explaining the crime of Guitau, but at the same time, while these persons said he must be of unsound mind, "off his base," etc., they were not in favor of absolving him from punishment. "Crazy, perhaps, but not so crazy that he should not be hung."

The impartial onlooker in the recent trial must have been struck with the fact that a great effort was being made to prove sanity, the presumption being in favor of insanity. The prisoner's conduct in court was so extraordinary and unlike that known of any sane man under similar circumstances, that it seemed inexplicable on any ground other than insanity, unless it were simulation, a belief in which was not generally credited. Had the actors in the tragically occupied different positions and to such an extent that the public feeling

<sup>1</sup> See *British Medical Journal*, vol. ii., 1875, page 493.

<sup>2</sup> Read February 25, 1882, before the Suffolk District Medical Society.

had not been aroused, and had the prisoner been examined by a Commission in Lunacy, or defended by able counsel, I, myself, do not doubt that he would at least have escaped the gallows.

In this paper I shall endeavor to briefly group together such data as go toward showing insanity, leaving out of consideration all arguments in favor of sanity, out of which the utmost has already been made.

In some ways even the investigation of the case of Guiteau is hedged in with difficulties; particularly is this so at the time of the commission of the homicide, for during its preparatory stages Guiteau was secretive and reticent, and no one was so placed as to be able to intelligently study his mental operations. The case was not one, however, of "transitory," epileptic, or other form of suddenly developed mania, but a form of insanity of long standing, and the cumulative evidence is therefore sufficient in itself. There are long periods when we know little of Guiteau. These periods no doubt might be much cleared up if it were not for the fact that but few persons have been found who, considering Guiteau of unsound mind, have been willing to come forward and boldly testify to that belief. Several persons testified to Guiteau's apparent sanity not long before the murder, but as these persons were laymen, of common intelligence, strongly biased by the general public feeling, and who had had only casual opportunities to talk with Guiteau, their evidence is not of great weight.

To begin at the beginning of the case, it is necessary to first look into Guiteau's heredity. We find one paternal uncle who died in an asylum and another who was a weak-minded drunkard. We find also two paternal cousins, one of whom died in an asylum. His mother had an acute brain trouble at the time of his birth and for several years after suffered from a nervous complaint. Several of his near relatives died of consumption. His father was a man of very marked peculiarities, in some ways perhaps overstepping the limits of sanity, and it is to the father that we may look as, in part, the cause of mental irregularity in the son. He was an unreasonable, exalted, religious fanatic, and early inculcated the vile and dangerous doctrines of the Oneida Communists in his son. Had his wife been willing he would have joined the Community himself. Though a man of honesty and principle in ordinary affairs, in religion he lost his power of sound judgment and common sense, and was willing to encourage and practice habits of gross immorality. It can be imagined that the religious instruction the son received from the father was not calculated to lift up or purify the soul.

The sister and brother of Guiteau, who were present at the trial in Washington, possess also a temperament in many ways similar to his father's and his own.

The sister has had attacks of *petit mal* and is said to have also had attacks of actual insanity. She is very emotional, rather exalted in religion, and lacking in tact and good judgment. She is possessed of the family volubility, and several times during the trial interrupted the proceedings, losing entirely for the moment her power of self-control. The brother possesses more common sense, but also at times loses self-control. For a man, he is unusually emotional and somewhat of a religious fanatic. When giving his religious ideas in court he rattled on with extraordinary volubility, and gave utterance to some remarkable doctrines about the seed of God and the

devil. His brother he thought belonged to the latter. Almost with tears in his eyes, he said that he had not treated his brother like a Christian, and would take that public opportunity to ask to be forgiven! Both brother and sister seemed to quite lose sight of the fact that their testimony might injure their brother, and, while many witnesses very evidently colored their testimony, they spoke directly from the bottom of the heart with intense earnestness. "Dead earnest" seems to be a general family watch-word.

Guiteau obtained a good common-school education, and at an early age helped his father, drinking in all the time his father's austere and licentious fanaticism. During early youth he practiced masturbation. For a few months in his nineteenth year he studied at Ann Arbor, there the teachings of his father had taken such hold of his mind that he renounced his books and in his twentieth year entered the Oneida Community.

At this time he was a quick-witted, sensitive, nervous, half-educated, vacillating, over-religious boy, knowing but little of practical life and ambitious to do great things. At the Community he absorbed everything that was bad, but found nothing to develop good. There he learned to believe he had found the kingdom of heaven on earth, and was taught that fornication, sexual indulgence, and yielding to the passions, if done with the sanction of the leader, Noyes, would be approved by God. Any education more calculated to destroy a correct moral sense and respect for society it is hard to imagine. At times Guiteau worked in the trap-shop and did fairly well, but he did not enjoy it, preferring reading and study. After a while he aspired to be a "Community leader," and usurp the power of the others. Finally, he found the Community too small for him, and in 1865 left and went to New York.

It was at this time he was filled with his wild scheme of starting a "Daily Theocratic Press." The publication of a little sheet called the "Circular," issued at the Community, and the religious life there, may have had something to do in originating the project in his mind. This plan resulted, of course, in utter failure, and he returned to Oneida, as he could find no employment in New York. Soon, however, he became disgusted with the Community again, and the Community also found him intolerable, and he returned to New York. There he at once sought a position as editor on the *Independent*; failing in this, he sought a similar position on the *Tribune*. Failing in this, he began to read vigorously on theology, law, and kindred sciences.

Finally he went through the farce of an examination in Chicago, and turned up as a lawyer. For the next two or three years he did well, earning a fair living, and supporting a wife. Then, however, he got tired of Chicago, and went to New York, where he espoused religion, committed adultery to get rid of his wife, brought a heavy suit against the *Herald*, and got finally thrown into jail for debt. Leaving New York and going back to Chicago, he again did well in law, but soon his mind became fixed on another grand newspaper enterprise. He proposed to buy the *Chicago Inter-Ocean*, and to put into it "the advertising patronage of the *Chicago Tribune*, the Republicanism of Horace Greely, and the enterprise of James Gordon Bennett." He wished to raise seventy-five thousand dollars to start the paper with, and applied to a man in Freeport for it, offering as an inducement to make

him governor of Illinois if he would let him have it. He was, of course, refused, but explained the refusal satisfactorily to himself by saying that this man had no political aspirations.

In 1876, after the failure of his last newspaper scheme, Guiteau turned his attention to religion, it seeming to be the only thing that was large enough to interest him. The New Testament was just the sort of reading that suited him, for he found in Christ an example in which poverty was glorified, and I have no doubt that he honestly excused himself for not paying his board bills on the ground that the Saviour had not where to lay his head, and paid no bills.

In the summer of this year Guiteau diligently studied the Bible, and prepared himself for his holy work, at the house of his brother-in-law. It was this summer when he seems to have shown symptoms of insanity, particularly in the direction of religion, and the case seemed such a clear one that the family physician advised sending him to an insane asylum, in which plan the family joined, and he would have gone had he not run away.

In October of the same year he joined Moody and Sankey, and was worked up to a high pitch of religious exaltation. During the following winter he wrote his lecture on the second coming of Christ. The idea of his lecture was that the second coming occurred on the destruction of Jerusalem, in the year 70, in the clouds directly over Jerusalem. The churches have been in error for eighteen centuries in supposing the second coming to be in the future. Guiteau, in his lecture and in his book, called *Truth*, and written some time afterward, apparently wishes to have these ideas considered as original. They are, however, quite similar to the views of Noyes, the Oneida leader, as expounded in the book called *The Berean*. As far as I could see Guiteau did not fraudulently use these ideas, but supposed that he had at least shared in their discovery.

With the utmost faith in his opinions, he went about lecturing, the laughing-stock of all his audiences, failing everywhere, and paying rarely a hall rent, few board bills, and no railway fares. Yet all the time he kept resolutely on, unconscious of the absurdity of his lecture, as well as of his daily dishonesty, and satisfied that he was working in the vineyard of the Lord, and teaching inspired truth. The exaltation and expansiveness of ideas of Guiteau were well shown in his announcement of his lecture in Boston in 1879: "Do not fail to hear the Hon. Charles J. Guiteau, the little giant from the West. He will show that two thirds of the race are going down to perdition." At this time Guiteau said he had challenged Ingersoll to debate, but he had not the courage to meet him. He stated that he belonged to the firm of Jesus Christ and Co., and God was his direct counsellor, and he did nothing wrong. His lecture was disconnected and rambling, and seeing that he was only laughed at he finally left the hall in disgust.

In 1879 he wrote *Truth, a Companion to the Bible*. He sent copies of this to prominent clergymen and editors, and sold copies in the street for about anything he could get.

In January, 1880, he became tired of "theology," and turned his attention toward politics. About this time he prepared his celebrated speech on Grant *versus* Hancock, changing the former name after the Chicago Convention into Garfield, and slightly altering the text.

This speech, which was six or eight small pages of trash, worthy only of a second-class pot-house politician, he sent to all the prominent politicians and editors in New York, and delivered in part to a crowd of colored men on one occasion. During the campaign in New York Guiteau was very familiar with the "big men," he says, and when they saw him they "pricked up their ears, and complimented him on his speech." It was on this miserable speech that he based all his important claims for preferment by the Republican party.

As early as October he began to clamor for his reward with as much assurance and complacency as if he had been a United States senator, and had stumped several States. He wrote to General Garfield that he was an applicant for the Austrian mission, and "expected to marry a lady of great wealth in a few days." This latter statement was a lie, but, taking into consideration the character of the man, was not surprising.

After the appointment of Blaine, Guiteau supposed he could not get the Austrian mission, and therefore, with his usual mental obliquity, decided that he would apply for the Paris consulsip. He called on the President, and with great satisfaction presented his speech to him, marking "Paris" at the end. The President would, of course, understand the extraordinary nature of his claims, and would be equally as keen in deciphering the meaning of "Paris." From this time he importuned both Blaine and Garfield, receiving nothing but evasive and discouraging messages, yet just as assured in his own mind that he should finally attain his end. He was totally blind to his own position in the matter, for the very simple reason that his power of reasoning was too defective to appreciate it. On his last visit to the White House the doorkeeper brought him word that it would be impossible to see the President "to-day." He regarded the word "to-day" as very significant, for if the President said he could not see him "to-day," he meant that he would see him some other time, and that was as much as to say, "and then we can arrange matters."

Shortly after this last visit his conception to remove the President came. This was at the time the rupture in the Republican party seemed the most serious. Guiteau industriously read all the papers, and felt convinced in his own mind that war was imminent, and possessing himself, as he thought, such vast political importance, he was greatly distressed. For a time his whole mind became absorbed in this great issue. Here was a President he had been particularly influential in getting elected actually proving a traitor to his own party. It showed the basest ingratitude, and was to him almost a personal insult. Thus it was that, aroused, exalted, stimulated by the outpourings of the press, he tried to solve the question, What should be done, and how could he aid in it? Suddenly there flashed into his weak, demoralized mind the idea of removal,—the "conception," as he always called it. Garfield out of the way, the field would be clear. Not only was there here an opportunity to restore the lost harmony to the country, there was also an opportunity to make himself a patriot equal to Washington and Grant. Such was the false reasoning upon which he proceeded to arrange for the terrible deed.

From the time of the "conception" down to the time the deed was done, there is, to my mind, no indication of malice, but all the evidence goes to show that there was in Guiteau's mind one grand, false idea of the

existence of a "political necessity," added on to which was the idea, not one necessarily of a simple craving for notoriety, that so great a deed would, as a matter of course, deserve the gratitude of the whole country. Having once established these false, or, to call them by their correct name, *insane* premises, Giteau calmly went to work, as most maniacs would under such circumstances, to arrange the details of the murder. It may be said here that during the trial Giteau's motives were very imperfectly analyzed, and attention was principally directed to the *details* of the crime. It should have been strongly brought out, as it has been on a hundred other occasions, that the lunatic's *premises* are generally what is wrong, his mode of reasoning or working on these premises may be absolutely perfect. Giteau was no exception to this rule. He worked at his plans in a business-like manner, slept well, ate well, and took his customary exercise. He recognized clearly what a storm of public indignation there would be immediately after the murder, and so made his arrangements to go to the jail. These arrangements were very simple and even boyish, and the only wonder is that he was *not* seized by a mob. He, however, arranged many details not directly concerned in the murder, which would serve as an explanation of his motives, or help to establish his patriotism. The newspaper clippings and his Address to the American People were for this purpose. "Nothing but the political situation last spring," he said, "justified the removal. The break in the Republican party was widening week by week, and I foresaw a civil war." The deed itself was the best proof of his patriotism, and to show how firmly he believed in it, he refused to take a quiet opportunity, when he would probably have escaped unharmed, but chose a most exposed place, and called on General Sherman for protection. Buying the ivory-mounted pistol instead of a wooden one, so that it would look better on exhibition with other important relics in the Patent Office (where articles belonging to Washington and other great characters are stored), was what the Germans would call a "colossal" belief in his importance as a patriot.

It will be remembered that Giteau had saved with his newspaper clippings a revised copy of his wretched little book called Truth. The revisions were simply a few alterations and additions that might easily have been made in a few hours. He saved this book, it seemed to me, partly as an evidence of his attainments, and partly as an evidence of his piety. Furthermore, he thought that the "removal" would enhance its value, and it would meet with a large sale. Any work of the *patriot* would become very valuable.

Better evidences of insanity than these just described, we imagine, it would be hard to find, but the courage of Giteau should not be overlooked at this time. Ordinarily, though he is an earnest, persistent man, he has lacked personal courage, unless, perhaps, as in his lecturing, when he acted more or less under the guidance of insane ideas. He states himself that he has dreaded street crowds, and has turned away when there seemed any indications of trouble arising. But in the removal of the President he had a courage he had never known before. He was "nerved up," as he thought. The true explanation seems to be that he was acting under the pressure of a delusion so strong that it carried him tranquilly on to its consummation.

Giteau is a man a trifle below medium size, weigh-

ing in perfect condition one hundred and forty pounds. He is pallid and rather delicate looking, though his health, he says, is good. He states that he has had syphilis and gonorrhoea, but this statement lacks verification. His pupils are unequal in size; the axes of the eyes are a little dissimilar, giving the eyes a vacant, glassy stare, which makes the expression of the face unnatural, suggesting to many persons depravity. His hair cut close to the head, and the moustache also cut short, and the beard worn long, give him an unshaven, unkempt look. Formerly he wore his hair long, and shaved smooth, *a la* Beecher, but having lost his confidence in Beecher, he now trims his hair in the opposite fashion. There is some asymmetry of the head, not, however, ordinarily noticeable. On the whole the *toute ensemble* of head and face is rather repulsive, suggestive to my mind of insanity rather than depravity. His smile is pleasant, even amiable. His teeth are quite regular, and well-cared for. His tongue presents nothing abnormal. His expression, when angry, is bad, reminding one of a wild beast. He talks very volubly, and gives the impression of frankness and honesty. When seen in the jail, and flattered a little, and made to feel his importance, his manners are polite and agreeable, but the quiet manner is quickly changed into one of excitement by the slightest reflection on his motives or character.

He told the experts, when they examined him in the jail, that he wanted to give them all the assistance in his power, and he seemed to actually have the power to look at himself as a third person. He had a certain chain of events in his past life arranged in his mind, which he thought had a bearing on the case, quite ready at his tongue's end. These events he would narrate willingly, but he would not for any one branch off on to a side subject. He felt that he had performed a noble act, and, in the same sense of the word, had been inspired to commit the deed for the good of the country. Though he was a patriot he must present some sort of a defense for the sake of appearances. At one time, I do not doubt, that he had thought that public opinion would exonerate him, and he would go free without a trial, but as this had not proved to be the case he must accept the defense suggested to him. All this, as a lawyer, he appreciated, and consented tacitly to another lawyer aiding him in court.

He gathered much information from questions asked him by the experts, which he made use of afterward as original. He would, however, in talking with them, angrily, as said before, disclaim anything which tended to belittle him or make him insignificant. He had been a friend of Conkling and Arthur, he was to be ranked with them; he might some day be president. He had been inspired on various occasions. He was a patriot suffering for his party, but glorying in his deed, which all stalwarts secretly applauded. He was much pleased with the idea that he was like St. Paul, and afterward likened himself to the apostle. He was willing and even anxious to be found insane, though not believing that he actually was insane. Looking impartially at the case he would say, "If the jury believe that I believed that I had a special inspiration to remove the President, then they must find me insane. I believe I was insane in law, but not in fact."

Giteau had in some manner conceived the idea that a "special inspiration" might be insanity, and he was willing to have what he called inspiration, which was the Oneida Community idea of inspiration, pass for

insanity. It was, however, a sane inspiration, the inspiration which he had been taught to use as a cant phrase to explain many acts of his past life. He well understood the limitations of such an inspiration, and could grasp the idea of using it as a defense. Guiteau said that he needed collateral evidence of his inspiration. Thus, if he prayed for something and got it, or prayed for strength to carry out some plan, and did so successfully, it was proof that God had given his sanction, or had *inspired* the work. The insane inspiration needs no proof. If it exists it is sufficient, and anything done on the strength of it will be entirely right. The divine command is alone necessary, and to try to prove that it was right would look like doubting that it was inspiration.

It was unfortunate that Guiteau's counsel laid such stress on inspiration, as its existence as a delusion could be easily disproved, and thus the most important element of insanity of the defense could be shattered. The real element of insanity hardly came to the surface, and the prosecution, therefore, had little to disprove beyond insanity in the father, and inspiration in the prisoner.

To say how insane Guiteau was or to what special class of the insane he belongs is extremely difficult. We have tolerably clear evidence that he has been insane much, if not most of the time, since leaving the Oneida Community. There is no single act, but it is all the acts and utterances of Guiteau, spoken and written, which together make up a case of insanity. Of many of the events of his life we have no history, and of others only a history from prejudiced persons. What we have got is sufficient, however, to enable us to make a diagnosis of chronic mania, similar to what I have observed in insane criminals. By this I do not mean exactly similar, but in which the general outlines correspond. In these cases insanity cannot be easily made out, but only after prolonged observation. Neither is intellectual impairment always easy to find, still such impairment does exist, and will in the course of weeks or months reveal itself. Such has been my experience with cases of so-called "moral insanity." Dr. C. F. MacDonald, Superintendent of the New York Asylum for Insane Criminals, at Auburn, has cited the celebrated case of Kate Stoddart as a somewhat similar instance. In this case it required the most searching examination in the beginning of her disease to discover its existence. To strangers she was pleasant and affable and very plausible in what she said about her imprisonment, and the injustice of keeping her in an insane asylum. Her self-possession was great when not aroused, and it is probable she could have gone into court and made a good appearance. Once aroused, however, she would indulge in violent and profane abuse and entirely lose her self-control. For years she had had a delusion that she was a lawyer and could argue her own case better than ordinary lawyers. This delusion could not be brought out unless she was carefully approached. To see the quiet, lady-like person with pleasant manners and bright smile, and the power of carrying on agreeable conversation, the ordinary observer could not have believed that she was licentious, uncontrolled in temper, possessed of delusions, and at times liable to outbreaks of almost homicidal violence. In this case of Kate Stoddart, it was only by long observation and the grouping of symptoms together that a correct diagnosis could be arrived at. It placed under restraint

these cases of chronic mania without marked delusions, but with undoubted moral and intellectual impairment, are very comfortable and often appear sane; their false beliefs are held in abeyance. The fire smoulders and sometimes almost dies away, but throw a sudden strain on them and the flame is roused into great activity.

Leaving out two or three years of Guiteau's life when, as a lawyer, he for a time seemed better than before or afterwards, we have a good account of a case of chronic mania, with occasional exacerbations. There is the exhalation, self-complacency, supreme vanity, seeking for notoriety, regardlessness of consequences, changeableness of purpose, inconsistency of action, hyperirritability characteristic of a form of mania with expansive delusions. The grand schemes which Guiteau endeavored to carry out, such as editing the *Independent*, or New York *Tribune*; founding the "Theocrat;" editing the new *Chicago-Intercean*; the desire for the Chilian Mission, etc., were all of them totally foreign to his education and experience, and absolutely impossible of accomplishment by him, and can only be properly and correctly regarded as illustrations of his delusional condition of mind.

The first appearance of recent delusions was seen in connection with the campaign of 1880-81. It was nothing less than a delusion, that he, an insignificant good-for-nothing, should, on the claim that he had once partly delivered a little, third-rate jumble of catchwords, which he dignified by the name of "speech," be entitled to one of the most important offices in the gift of the government. Such a claim shows an insane method of reasoning, as well as a lack of perception and judgment.

His belief, which was undoubtedly honest, that he was of equal importance with Conkling, Arthur, etc., is a part of this general delusion and grows out of his insanely exalted idea of his own importance, for there is no evidence to show that he was any more than tolerated by them.

It was further an insane belief or delusion that Guiteau entertained, that there *was* a "political necessity" to destroy the President to save the country from a civil war, and no sane mind would have reasoned itself into the belief that murder would have averted the crisis. The most stupid of men would have seen that the murder of the President would inflict an injury a thousand times greater to the country than such a controversy as was going on between a small number of men in the Republican party. The strength and absurdity of this delusion is shown by the confidence that Guiteau felt that he should receive support from the stalwarts and be honored as a patriot when his true motives were known.

The conduct of Guiteau in court affords to my mind strong corroborative proof of his mental unsoundness. He showed himself to be quick-witted, sharp, gifted with an excellent memory, unscrupulous, uncontrolled in temper, and almost entirely lacking in judgment and discretion. His controlling idea seemed to be to guard his reputation as a man of purity, ability, high attainments, Christian virtues, and political importance. It made no difference what was said on either side; no matter whether it injured his case or helped it; whether it insulted his counsel or the other side. Hit or miss; friend or foe; with the true indifference of the lunatic, he made his criticisms. The dignity of the court-room; the threats of the judge and bailiffs, of the

district attorney, or the United States Marshall, he was indifferent to all. That instinct in the human breast which makes us bow before the majesty of the law and tremble at her bidding was not within him. With the volubility and lack of self control of the insane man his voice was heard above all others, and it must be remembered that this was the case, from the beginning to the end of the trial, with everybody, and nothing could have silenced him in all probability. An exhibition in all ways so extraordinary as the conduct of Guiteau at his trial is not, to my knowledge, on record, and it is not too much to say that it would be a disgrace to American jurisprudence were it not explainable on the ground of insanity.

The trial reminded me of what a trial might be if a patient with chronic mania were brought in from an asylum and tried for murder. Provided he were a bright, intelligent man with delusions of self-importance, of such a nature that they had had a bearing on the crime, his conduct might have been in many ways similar to that of Guiteau.

In the writings of Guiteau may be found evidences of exalted and expansive ideas, as well as in the acts above described. As far back as 1859, when at Ann Arbor, he wrote, "I confess Christ in me, my ability to confess that my treasure is in God—that is, I have no love or affection in the world, through Christ. There is where we all must come, that expect to be saved, for we will be saved through Christ, or damned by him." At Oneida, in 1861, he said, "I was attracted here by an irresistible power, which I did not feel at liberty to disobey." In 1865 he wrote his celebrated Hoboken letter, in which he says, after describing his plans to establish the "Daily Theocrat," "However presumptuous it may seem to confess the truth about myself, I say boldly that I claim inspiration. I claim that I am in the employ of Jesus Christ and Co., the very ablest and strongest firm in the Universe and what I can do is limited only by their power and purpose. God is my employer. I know that he will sustain me. He has furnished what money I have." This letter bears a very strong resemblance to the writings of Guiteau at the present time. There is the same idea of inspiration and exaltation, and the same easy way of leaving money matters to the Lord. It has struck me as remarkable to find so much consistency in what he has written. In 1867 he said "that he was under a constant pressure to write" ("pressure" is a favorite word of his still). In 1877 he sent out a letter from the Chicago jail, asking for assistance, but filling it with statements about his character, his love for God, for Christ, etc.

There is, after this time, a break in the letters, as most of them were destroyed in the Chicago fire. His writings begin to come thick and fast, however, at a later period, beginning with his lectures. In these later writings he shows a form of mania for writing common to many lunatics. These writings are comprised in part of his lectures, his book, his speech, his numerous letters to Garfield and Blaine, his address to the American people, his *Herald* autobiography, his opening address to the jury, his Christmas address, and his closing address. The last comprehends almost everything he has said during the trial in other addresses, and contains a little new matter. It is written in the grandiloquent, high-sounding manner characteristic of him, and shows how he has gone from one point of his defense to another, making use of such new ideas as pre-

sented themselves in the evidence, retaining, however, the one central idea of his own patriotism and greatness. He says, among other things, that "General Arthur is a good man every way. I happen to know him well. I was with him constantly in New York during the canvass. So with General Grant, Conkling, and the rest of those men. They have not taken an active part in my defense, because it would not be proper, but I know how they feel on this case." He interlarded his statements with a variety of silly, jocose letters and telegrams he had received complimenting him on his conduct and admitting his greatness. These were sent him as jokes, but he received them in earnest, as tributes to his importance. Here Guiteau follows the usual course of the insane person, and explains all circumstances which do not accord with his false theory in a purely fictitious manner, so that every inconsistency is overlooked or explained in a satisfactory manner.

This sentence in the Address to the American People of June 16th is a good illustration of Guiteau's false belief and exalted method of expression: "In the President's madness he has wrecked the once grand old Republican party, and for this he dies. The President's nomination was an act of God; the President's election was an act of God; the President's removal is an act of God."

In the way Guiteau uses his writings he resembles also many of the lunatics who possess this mania for writing, especially those who have an exalted form of mania. These persons address voluminous documents to various distinguished personages, and though they are never answered the writers seem perfectly satisfied. They often carry extensive petitions or letters in their pockets, and entrust them to any visitor they may see to take them to the President or other important person. For years they will continue to forward these documents, expressing but little regret at getting no response. The mere act of writing seems sufficient to satisfy the ambitious desire of the writer, and the changing undercurrent of his delusion renders him oblivious to the ordinary course followed in letter writing. I have known lunatics who carried numerous documents on their person, concealed them in all sorts of out-of-the-way places, and sent them out of the asylum openly and surreptitiously on every opportunity, who would not have been recognized as insane had they not possessed this writing mania. In these letters, addresses, or proclamations their delusions would generally show themselves.

Guiteau followed the usual course of these maniacs, and was equally ready on every available occasion to produce some document, letter, or pamphlet wherein was plainly shown the truth of all his claims. He seemed never to be more supremely happy than when he had an opportunity to show or to read from these writings. Forgetting himself for the moment, he became carried away by his own eloquence. Perhaps no better example of the insane use to which Guiteau put his documents can be cited than when he left his speech with Garfield, marking "Paris" at the end. That speech, he thought, was enough to open the doors of paradise, and a comparatively small man like the President of the United States would certainly be overawed by it. It was hardly necessary, after this proof of his ability, to say anything more about his application for office, but he would mark "Paris" as a delicate reminder of his preferences for the French consulship.

From this short analysis of the case of Guiteau it will be seen that I recognize his insanity both before, at the time of the homicide, and since. While the theory of limited or partial responsibility has at times seemed feasible in his case, if any, I think that on the whole it should be rejected. It is dangerous ground we tread on when we attempt to split hairs in weighing the moral capacity of the lunatic. And it is still more audacious in a case like that of Guiteau to usurp the prerogative of the Almighty and sacrifice a human life to the quibbles and vulgar prejudice of a mere handful of men.

It will be much more to our credit as a country, and much more in the interests of humanity and progress toward better things, if the miserable Guiteau can be saved from the gallows and be placed for life in a properly regulated criminal lunatic asylum.

### ON THE EARLY TREATMENT OF PROSTATIC OBSTRUCTION.<sup>1</sup>

ABSTRACT OF PAPER READ AT THE MEDICAL SOCIETY OF LONDON, MARCH 13, 1882.

BY REGINALD HARRISON, F. R. C. S.,  
*Surgeon to the Liverpool Royal Infirmary.*

It may be generally stated that of males who have passed fifty-five years of age about one third, sooner or later, have enlargement of the prostate, of these about one half suffer therefrom, though so long as micturition is efficiently and painlessly performed, there are seldom grounds for complaint.

It is exceedingly interesting, as indicating how relief may be afforded, to analyze the cases where the prostate is large but does not obstruct; there are at least two conditions explanatory of non-interference with micturition under these circumstances.

First, where the hypertrophy is towards the rectum, and the relations of the prostatic urethra are not altered; and, second, where the hypertrophied gland is lobulated, and channels are left between the masses along which urine flows without interruption. A careful consideration of these conditions have suggested that they are capable of artificial production to a useful extent.

The teaching of the present day is, however, to the effect that mechanical treatment is not to be employed until either retention occurs or the bladder becomes inflamed, then such means may be resorted to. It was asked why the same treatment should not be applied as in the case of urethral stricture. The objection generally advanced is that irritation will be produced. It was urged that there was no evidence in support of this objection. On the contrary, the prostate was about the most long-suffering organ in the body, and though it was subjected to a great variety of mechanical expedients, in lithotomy and other operations, it rarely became inflamed. It might just as well be said that because strictures were found occasionally to be exceedingly irritable, treatment was to be postponed until retention of urine or cystitis were provoked. But if intolerance to early mechanical treatment were proved, it was only postponing the day until the necessity was greater and the difficulty more apparent. If there was danger of irritating the prostate, it was none the less because its size was larger.

<sup>1</sup> From advance sheets.

With the view of obtaining similar conditions to those occurring naturally in large prostates, where there is no interference with micturition, a mode of treatment with specially-adapted bougies was described. The instruments are gum-elastic, two to four inches longer in the stem than usual, with an expanded portion an inch from the tip, which is made to enter the bladder. In this way the prostatic urethra is subjected to pressure on the insertion and withdrawal of the instrument.

As a rule, if dilatation is not too rapidly proceeded with, no irritation is aroused. On the contrary, greater toleration of urine follows, owing to the ease and completeness with which the bladder is then emptied.

In a few persons it became necessary to establish a state of instrumental toleration, the frequency for doing this, as a rule, depending more on the manipulator than on the instrument. In some individuals intolerance of urethral interference was entirely due to the condition of the urine. Such sensitiveness had been traced to the presence of uric acid in unnatural quantities and form. On the correction of this patients previously intolerant of instruments were found capable of undergoing the necessary mechanical treatment with the greatest advantage.

In advocating the early treatment of prostatic obstruction by the means referred to the author had already had sufficient proof of its efficacy. He had demonstrated that the regular use of the dilators was capable of so moulding the enlargement as to prevent obstruction. Cases were under observation where the symptoms indicated that an impediment to micturition was commencing to form. Such patients in this way regained the power they were beginning to lose. In bringing forward his views on the subject Mr. Harrison did so with the feeling that little had been yet done towards preventing the progressive development of a condition which was often followed by very distressing, and sometimes embarrassing, results—results which we knew of and stood by to palliate, though we had hitherto been helpless in preventing them.

### RECENT PROGRESS IN THEORY AND PRACTICE OF MEDICINE.

BY GEORGE B. SHATTUCK, M. D.

#### A STUDY OF THE PERIODS OF INCUBATION OF THE COMMUNICABLE DISEASES.

Dr. B. W. RICHARDSON read a paper with the above title before the Medical Officers of Health Society at its meeting May 20, 1881, an abstract of which we reproduce.<sup>1</sup> The five following points were brought forward:—

(1.) What is the precise application of the term "incubation," and to what diseases should it be applied? (2.) What is the state of absolute knowledge of the periods of incubation of the more common communicable diseases? (3.) In respect of differences of opinion on this subject do they depend on fault of observation, or on the circumstance that there are in the same diseases varying periods of incubation, the variations being under no as yet defined law? (4.) If it be found that there are differences of periods in the same diseases, upon what do such differences depend? (5.) What are the practical lessons which arise from the facts we at present possess, and to what extent may our knowledge be rendered available in the prevention and treatment of disease? On the first of these points Dr. Richardson said that, simple as the question seemed to be at first sight, it was by no means simple. We reduced the diffi-

<sup>1</sup> *Lancet*, 1, 392, 1881. *Med. Press and Circular*, 1, 461, 1881.

culty by limiting the term to those instances of disease in which, after a certain specific poisonous particle had been taken into the living body, certain indications of the action of that specific poisonous matter have been manifested — that is, the period between the introduction of the poison and the manifestation of its action is the period of incubation. We fail, however, to be unanimous in the question, What is the accepted first sign of such manifestation? After citing several illustrations of this diversity of view, Dr. Richardson, by exclusion threw out local symptoms as insufficient proof, together with pain and fever, but accepted as the safest phenomenon indicating that the incubation is declared that sudden vibration between cold and heat which tells the break of continuous action between the nervous and the vascular systems to which we give the name of chill or rigor. The author next added the list of diseases, twenty-five in number, which present a stage of incubation. Under the second head, the range of period of incubation in the different diseases, the diseases were classified into five groups, according to the time of incubation in each case. The classification ran as follows: (a) Shortest incubations, period one to four days: Malignant cholera, malignant pustule, plague, dissection wound disease, catarrh, if it be communicable. (b) Short incubations, period two to six days: Scarlet fever, rosolia idiopathica, diphtheria, croup, influenza, pertussis, erysipelas, glanders, yellow fever, grease, larc, pyæmia, procerpal fever, dengue. (c) Medium incubations, period five to eight days: Relapsing fever, vaccinia, variola by inoculation, gonorrhœa. (d) Long incubations, period ten to fifteen days: Small-pox, variella, measles, röteln, mumps, typhus, typhoid, or enteric fever, malarial fever. (e) Longest incubations, period forty days or longer: Syphilis, hydrophobia, in which the range may be from seven days to months, or even years. From these general rules Dr. Richardson proceeded to state the exceptions to them in detail, the variations being most marked in class b, where the periods of incubation are short. Under the third head of his discourse, on the reason of differences of opinion as to the periods of incubation, the author held that such differences are traceable to four sets of causes. First, that we have not been, up to this time, agreed as to the full symptoms that indicate the stage when incubation is complete; secondly, that until lately we have not tried to classify diseases according to the rest of incubation; thirdly, that we have attached too much importance to the exceptional phenomena of incubation; fourthly, that we have been too prone to connect diseases together which are in some respects similar, but which in regard to incubation are most dissimilar. Now that we are approaching nearer to the truth we may soon be able to classify and understand the exceptions from the ordinary or natural rule of incubation. He proceeded to consider the circumstances which may lead to differences in periods of incubation in the same affections, and suggested that as it was not known that inoculation of a poisonous particle shortened the period of incubation, so it was possible that in some cases where the poison was absorbed an accidental inoculation might account for variation of time of incubation. Again, the poison might be absorbed in one case in a form of diffusion reader for absorption in some cases than in others. But the great cause of difference was traceable to individual susceptibility, together with physiological peculiarities dependent on season and the meteorological conditions which so modify the action of the organic poisonous material. The paper was brought to a close by a review of the practical lessons which spring from the study of incubation. The points here advanced may be briefly stated as follows: If we could arrive at definite evidence on which we could all rest, that the incubation of a disease is proved by the occurrence of a certain symptom or definite class of symptoms, we could account for much that is mysterious. For example, in vaccinia can it be that, trusting entirely to the local phenomena, we sometimes have an apparently good vaccination which never has inoculated at all? If that be so, there is a reason why a person who seems to have been thoroughly vaccinated should still remain susceptible to small-pox. The suggestion, though it stands alone, is all-sufficient to indicate the practical importance of proving inoculation before pronouncing it to be a sure protection upon the evidence afforded by some but not all the symptoms of a communicable affection. The division of diseases of the communicable type into different classes or groups according to the stage of incubation which is presented is a practical acquirement of the most important every-day value, both in curative and preventive science. It is quite true that to know when to retain at home a sick person laboring under communicable disease, when to send him from home, and when to separate him from the actual or presumably unaffected, is a direction of practical skill as eminently creditable to the profession of medicine as it is useful to the public. To remove

the healthy from the affected is good practice in the case of all the diseases of the first and second of the groups of the quick and short incubation series. To remove in the third series may be sound practice. To remove the fourth or long incubation class is less important, and may be a practice that is quite at fault and prejudicial. Lastly, from the study of the incubation period we learn how to assign the best means of disposing of the affected during convalescence. It seems to be a true reading of natural phenomena that the diseases of short incubation have a prolonged convalescence, and remain long sources of communication, while the diseases which show a long incubation give a quicker convalescence, and a more rapid freedom from danger as a centre of communication of disease. Here there is a practical lesson that cannot well be overestimated. Keep the cases of short incubation at home. They will infect others and be injured themselves by removal.

#### CONCERNING THE ACQUISITION BY THE SYSTEM OF A TOLERANCE OF SPECIFIC AND OTHER POISONS.

Dr. G. M. Sternberg, discussing the explanation of the protection from subsequent attacks, resulting from an attack of certain diseases and of the protective influence of vaccination against small-pox, rejects the old idea that some special pabulum in the system is exhausted by the specific poison, and argues in favor of the more acceptable theory that during a non-fatal attack of one of the specific diseases the cellular elements implicated which do not succumb to the destructive influence of the poison acquire a tolerance to this poison which is transmitted to their progeny. The known facts in regard to hereditary transmission by cells, whether in the vegetable or animal kingdom, of acquired properties fortifies a belief in the truth of such a theory, summed up as follows by Dr. Sternberg: Acclimation, inoculation by attenuated viruses, and an attack of one of the specific diseases, should all be placed in the same category so far as the explanation of the protection afforded is concerned, and the explanation of this phenomenon is to be found in the peculiar properties of living protoplasm which enables it, within certain limits, to adapt itself to varying conditions and injurious influences, and to transmit the impression or modification received in doing so to its offshoots, which continue to perform its functions during the life of the individual.

#### A THEORY OF THE ADAPTATION OF GERMS TO SOILS, AND OF IMMUNITY FOLLOWING INOCULATION.

Dr. Grawitz, of Berlin, has been engaged for seven or eight years upon a series of experiments which have an interesting practical bearing upon theories of the immunity following exposure to the influences of poison by inoculation or otherwise. Occupying himself with the larger fungi, — such as aspergillus and penicillium, whose spores are several hundred times the size of a micrococcus, — he obtained results which he made the subject of a paper in Virchow's *Archiv* (Band 81), and subsequently of an address before the Congress of the German Surgical Society last April. This address, published in Langenbeck's *Archiv* for July, 1881, was to be the prelude to further and fuller reports of his observations. In the mean time Grawitz's published results and deductions therefrom have been attacked, and their value badly impaired by Koch, Gaffky, Lichtheim, and Löffler,<sup>2</sup> and a lively discussion, started in the Berlin Medical Society and Berlin Health Bureau, found its way into their *Transactions* and into the medical journals.<sup>3</sup>

<sup>1</sup> American Journal of the Medical Sciences, April, 1881.

<sup>2</sup> Mittheilungen aus dem Kaiserlichen Gesundheitsamte, Berlin, 1881.

<sup>3</sup> Berlin. klin. Wochschr., Nos. 45, 46, 47, 52.

The whole has an instructive bearing upon the easy sources of error which surround the worker in germs, even when of so large a size as the fungi, and upon the relation between special germs and specific diseases.

Grawitz believed that his long-continued and extensive experiments justified him in announcing that certain fungi, ordinarily harmless, and not developing in the blood of warm-blooded animals, could, by cultivation and adaptation, be changed in character in such a manner as to flourish in the system after inoculation, and to produce fatal consequences; from being simple that they became malignant organisms. These results were announced as the basis of "a theory of adaptation of mould-fungi in general." The further application of such views, if well established, to the poisons of such diseases as typhoid fever and cess-pool fever, scarlatina, and diphtheria would be immediate.

On the other hand, "It occurred to Dr. Grawitz<sup>1</sup> that, as the fungi could be adapted to a higher degree of vital energy, enabling them to enter into a successful struggle with the tissues for existence, so the less resisting of those tissues might gradually be adapted to a higher degree of that special energy needed to resist the fungus. He sought to bring about that adaptation of the more helpless tissues in two ways: first, by introducing into the body a considerable quantity of the partially adapted (or half malignant) fungus, and, secondly, by introducing a very small quantity of the perfectly adapted (or highly malignant) fungus; in the first case, the vital powers of the fungi would be so weak that even the kidney would make existence hard for them; and, in the second case, the quantity of the fungus would be so small that the few centres of fungus growth resulting would not endanger the life of the dog or rabbit so inoculated. These problematical adaptations of the tissues having been duly brought about, Dr. Grawitz proceeded, after four to six weeks, to give the same animals such a dose of malignant fungus as would ordinarily have killed them in three or four days, and as, in fact, did kill the control-animals beside them. In the case of those which had been adapted or made accustomed to a large quantity of weak fungus the result was that they either resisted entirely the full dose of malignant fungus or that the due effects of the latter were delayed twelve or fourteen days. In the case of the animals whose tissues had been habituated by means of a small dose of the malignant fungus not a single one of them succumbed. A number of these latter were killed after a time, but neither the kidneys nor any other favorite seat of the fungus growth showed the ordinary yellowish nodules. It is worthy of note that protection against the malignant aspergillus was afforded not only by the slighter inoculation of the same fungus but equally through previous adaptation or habituation with penicillium and orlunum lactis. As a controlling experiment the protective influence of uncultivated aspergillus and penicillium was tried, and was found to be nil.

"Such is the theory of Dr. Grawitz to account for the success of the practice of vaccination and of inoculation for anthrax and fowl cholera. A certain fungus can be, as it were, educated up to living inside the human body, and, in like manner, certain tissues of the human body, otherwise an easy prey to the fungus, can be educated up to resisting the latter. That seems only fair, and as it should be, *se non e vero, e ben trovato*. The body has, further, the best of it, in that it takes

only one trial to adapt its tissues, while many successive cultures are required to adapt the fungus. In both adaptations heredity comes in; the gradually acquired invasive properties of the fungus are retained by successive crops of spores for many months, and the more rapidly acquired resistant properties of the tissues are transmitted to successive generations of cells for a corresponding period. After a time the penicillium or aspergillus loses its acquired power of living in the body, and returns to its natural state of a mould living on bread; in like manner the resisting power of the cells of the body is weakened in the course of their successive renewals, and is ultimately lost."

But, as we have stated, these results and the consequent Anpassungstheorie der Schimmelpilze were hardly in type before other investigators, and among them so eminent an authority as Koch, detected fatal defects in Grawitz's methods, his cultivations were not strictly guarded against mixed races of fungi, were not "pure," and a fungus — aspergillus glaucus — which he had treated as innocent under ordinary conditions was shown to possess malignant properties without being subjected to even so mild a form of cultivation as an increase of temperature.

The net results of this controversy and these labors seems to be that Dr. Struck, director of the Royal Health Bureau, Berlin, thinks that the present state of our knowledge may be expressed thus: "that the malignant fungi are specific organisms, which are begotten by and beget only their like," and R. Koch somewhat more guardedly though as positively announces that the reverse has yet to be proved.

The study of fungi, however, indirectly had the result of leading Israel, a fellow laborer of Grawitz, to the description of actinomycosis as a disease in man, and his investigations in turn suggested to Poufick the existence of precisely the same disease in cattle.

#### DIPHTHERIA.

Drs. Wood and Formad reach the following conclusions in summing up the results of their investigations into the nature of the diphtheritic poison in their report to the National Board of Health.<sup>2</sup> They believe that future research will show that micrococci cause diphtheria by their power of forcing their way into the tissues, and by their own excessive vitality overcoming the vitality of those tissues, changing their nutritive processes, destroying them, and finally getting into the blood itself, destroying its white corpuscles, and obstructing the circulation, but it cannot be considered positively proven at present that the micrococci themselves are the essential poison and not simply the carriers of the poison.

Their observations lead them to the conclusion, in opposition to Curtis and Satterthwaite, that after a time the diphtheritic membrane, even if kept perfectly dry, does lose its contagious powers. The following facts they consider as established:—

The micrococci of diphtheria do not differ, so far as observed, from the micrococci of furred tongue, etc., except in their tendency to grow in culture fluids.

The micrococci of furred tongue or ordinary sore throat have a less tendency to grow under culture than have the micrococci of endemic non-malignant diphtheria.

The micrococci of endemic or non-malignant diphtheria have a much less tendency to grow under culture than have the micrococci of malignant diphtheria.

The rapidity of growth of the micrococci is in direct propor-

<sup>1</sup> British Medical Journal, vol. ii., p. 785, 1881.

<sup>2</sup> Supplement No. 17 to National Board of Health Bulletin.

tion to the malignancy of the case yielding them, and its contagiousness.

On exposure to the air diphtheritic membrane of the most virulent type loses its contagious power, and the micrococci *pari passu* lose their power of growing in culture fluids.

Under successive generations of artificial culture the diphtheritic micrococci lose their growth, activity, and also their power of infecting the rabbit.

It has not been experimentally directly proven, but it is a necessary inference from the two facts just stated, that under certain favoring circumstances the sluggish micrococci puts on growth—activity, and, in all probability, *poisonous properties*.

Every grade of case can be found in man from an ordinary sore throat, through simple pseudo-membranous angina and tracheitis, up to malignant diphtheria.

Any inflammation of the trachea of sufficient intensity may cause the formation of a pseudo-membrane.

A case may begin as one of sthenic "pseudo-membranous croup" and end as one of adynamic "diphtheria," with blood poisoning; and in cases of this character not infrequently no exposure to contagion is discoverable, and there is clinically every reason to believe that the blood poison has been developed within the body of the patient. The theory of the disease which they would deduce from these facts is that the micrococci, which directly or indirectly causes the diphtheria, is not a specific organism different from that common to healthy and inflamed throats, but is an active state of that organism; that certain circumstances outside of the human body are capable of throwing this common micrococcus into this condition of active growth and engendering an epidemic of diphtheria. When diphtheria is thus epidemic the micrococci light upon a throat, and if the throat have little resisting power, as in the child, inflame it or increase a catarrh already existing into a violent inflammation, and also rapidly enter the blood and cause systematic poisoning.

On the other hand, a catarrh in a weakly subject may, in the beginning, be simply an inflammation from cold, but the ordinary micrococci in the throat or mouth, favored by the special conditions, etc., may gradually change from the dormant to the active state, and by and by act upon the throat, and at last force their way into the system, and a self-generated diphtheria be formed out of a "cold."

It has already been abundantly proven, they think, that there is no specific character detectable in the micrococci of diphtheria. The history of wounds infected with diphtheritic poison and of those infected with hospital gangrene lends further confirmation to the idea that diphtheria and certain other septic diseases are really different manifestations of the one affection, the difference in symptoms depending rather upon the difference in the location than in a difference of the nature of the septic process. In order to test this they made a few experiments.

Drs. Wood and Formad very properly do not claim that these experiments are sufficient to establish the identity of diphtheria and other forms of local gangrene, but consider that they certainly favor such a belief.

In concluding their report they suggest the great necessity of further research, especially upon the relations to diphtheria of scarlet fever, pyæmia, erysipelas, and various septic diseases in which micrococci that seem to be similar to those of diphtheria occur.

## Hospital Practice and Clinical Memoranda.

### TWO CASES OF PROBABLE TRICHINOSIS.<sup>1</sup>

BY C. W. WOOLDRIDGE, M. D.

On the 26th day of February, 1880, I was called to see Mr. Henry Miner, a laboring man living in the village of Montague, Michigan. I found him suffering from fever and a general sense of discomfort, but his request when I came into his presence was that I should do something for his eyes, the tissues about which were greatly swollen while a general puffiness seemed to be spreading over his face.

<sup>1</sup> Read before the Suffolk District Medical Society, February 25, 1882.

There was no appearance of inflammation, nothing that would serve to localize the trouble, no pain other than a general sense of discomfort and weakness, which the fever that he was suffering from might readily account for, and the stiffness about the eyes due to the oedema which he had supposed to be the seat of the disease, but which to my mind appeared to be but a symptom of some general disturbance.

To make the matter more peculiar, Mr. Miner's brother-in-law, a youth of about eighteen, living in the same house with him as one of the family, was suffering from exactly the same symptoms, with the difference that in his case they were a few hours behind in their development. This to my mind rendered improbable in the outset any diagnosis which I might otherwise have tentatively adopted. I could make nothing of it; however, as it was necessary to do something I gave them a little bitartrate of potassa as a safe eliminative and awaited developments. The next day I found the fever about the same, the swelling had become more general, involving the face and neck, while the hands and arms also showed some puffiness. It was not easy to tell which of my patients was the sicker man on this occasion nor afterward; they were alike. On this second day they complained of a more painful sensation over the stomach than before, and a diarrhoea had set in that was out of all proportion to the medicine that I had given them, though at first I was inclined to attribute it to its action. The third day there was but little change. They spoke of a painful stiffness of the neck, which either on this day or the day afterward involved the respiratory muscles also, causing a difficulty of breathing. The swelling was not much changed, but if anything it was a little more general, while that about the eyes was less marked.

On the fourth day the swelling had begun to diminish, but the fever continued and likewise the diarrhoea. By this time, too, their complaints of muscular pain were much more decided. They complained of pain, stiffness, and weakness, especially in the neck, but also in the arms and over the epigastrium. This painful stiffness increased for some time and became more general until it was painful to move at all, but the pain was never acute. It was not until this muscular soreness became somewhat prominent in the complaint of my patients that the thought of trichinosis occurred to me, and I began to look up the subject. The result of my doing so was that it became exceedingly probable to my mind that it was trichinosis that I was dealing with, and the next time I saw my patients I told them that I believed they had eaten a meal of raw ham, pork, sausage, or something of that kind a short time before they were taken sick. They immediately admitted that such was the fact, but it was several days before. They could not remember exactly the day, but they two had come in hungry from their work and had made their supper from a fresh ham which they had eaten raw with vinegar and pepper, making a hearty supper of it. They were too late for the regular meal and no one else ate with them. The rest of the ham had been cooked and eaten, not even the bone could be found. They had purchased the ham at a grocery store in the village, to which I went to see if I could find any trace of the hog from which it was taken. I found that according to their books Mr. Miner had purchased a ham of them about two weeks before his sickness, a rather earlier date than that assigned approximately by him. They remembered it; from his

weight they thought it was part of a hog which they had purchased about that time from a farmer in the neighborhood, but of that matter they could not be certain, and they had none of it left.

The subsequent course of the disease in my patients was that after ten or twelve days there was a gradual improvement, but long after all active disease seemed to have ceased they were nearly helpless, and two months afterward they were but beginning in a feeble way to try to do a little work.

I was very desirous of obtaining evidence of the correctness of my diagnosis that could not be questioned, and for this purpose I persuaded Mr. Miner to let me cut into his shoulder, and remove a small portion of muscle for examination. This I did on the 18th of March, twenty-two days after the beginning of the sickness, removing a minute portion of the deltoid.

I considered that the chances were against my finding trichinae there, even allowing their existence, since I could not expect them to be so numerous in my patient, who was recovering, as they would probably have been in a fatal case, nor in that particular muscle as in others not so conveniently situated for examination in a living man. Nevertheless it was possible that I might find some. Accordingly I examined the specimen I had obtained carefully with the microscope, and always found on the slide distinct specimens of striated muscular fibre, but no trichinae.

It will be proper here briefly to review the natural history of this disease, which has attracted so much attention of late by reason of its having disturbed our commercial relations with Europe. Aitken says: "The disease begins a few days after eating the meat in which there were trichinae, with loss of appetite, general discomfort after eating, irritation of the stomach, vomiting, and diarrhea. These symptoms last from four to eight days, till the progeny are born. Severe symptoms may set in and continue until the parasites are encapsuled if not previously fatal. There are continued diarrhea and fever, oedema of the eyelids, also pain, or at least a painful sensation of weakness, in the limbs, oedema of the joints, sometimes of the whole body, difficulty in moving the tongue, profuse, clammy perspiration, and the patients who do not become convalescent die either unconscious with symptoms of typhoid fever, or, in a few cases, remain conscious to the end, complaining of inability to breathe freely."

Professor Dalton, speaking of the symptoms in two cases which he studied in 1861, which proved to be trichinosis, says, "These symptoms were abdominal pain and diarrhea soon after eating the suspected food, followed by oedema of the face and diarrhea. Niemeyer speaks of *insidious* trichinosis, in which the preliminary symptoms are absent, and the secondary symptoms of the disease, oedema, fever, and the symptoms characteristic of the trichinotous myositis are the first to be developed. "But," he says, "far the greater number of patients complain in from a few hours to a few days after the poisoning, when the young brood have been hatched, of severe pressure in the stomach, of eructation, and nausea, combined with a feeling of great heaviness and depression. There is almost always diarrhea accompanied by more or less severe colicky pains. These symptoms are soon accompanied by those of the entrance of the trichinae into the muscles, vague pains, and a feeling of stiffness, as well as a peculiar oedema of the face, affecting the eyelids."

Renz, as cited by C. W. C. Glazier, M. D., in the report on trichinae and trichinosis, prepared under the direction of the United States government, 1881, mentions the possible division of the disease into four stages: first, the prodromal; second, the stage of intestinal irritation; third, the stage of muscular irritation; and, fourth, the stage of retrogression and convalescence; but adds, "Such a stereotyped division does not always correspond to the course of the disease, nor could it reasonably be expected that it would. Of the four possible stages," he says, "none except that of muscle irritation is entirely certain." Krantz observed a period of incubation lasting from a few hours to forty-three days, and he had cases in which there were no disturbances of the digestive functions. The most important and constant symptoms of the second stage, he says, "are oedema and perspiration. This stage is ushered in usually with oedematous swelling of the eyelids, which often spreads to neighboring parts, and sometimes is associated with a light form of conjunctival catarrh." Heller, in Zeimssen's Encyclopaedia, says, "With the appearance of oedema of the face and eyelids on the seventh day trichinosis must be naturally suspected. The further progress of the disease is so characteristic that the diagnosis can scarcely remain in doubt." He also says, "The diagnosis becomes indisputable on the discovery of a single intestinal trichina in the stools or upon the observation of muscle trichinae in excised portions of muscles, but a negative result of the examination of the discharges and of small portions of muscle is no evidence against the correctness of the diagnosis, while it is to be remembered, on the other hand, that a positive diagnosis of the trichina disease may be made without these observations."

I desire in conclusion to express the opinion that mild cases of trichinosis occur much more frequently than they are recognized. The cause is found everywhere, and there is no practical way in which it can be detected and avoided. If people would be safe they must cook their meat.

I would also call attention to the fact that Dr. H. I. Bowditch is among the earliest investigators of this disease, having independently discovered it in a patient, and published an account of it with illustrations in 1841, nearly twenty years before its origin began to be understood; although Owen, of London, and others, as Dr. Bowditch reports, had seen the animalcule without having connected them with any particular food.

## BOSTON LYING-IN HOSPITAL.

CASES IN THE SERVICE OF W. L. RICHARDSON, M. D.

REPORTED BY F. B. HARRINGTON, M. D.

### CASE I. PUERPERAL INSANITY.

H. E., is a married woman, twenty-five years old who came to the hospital and was delivered of her third child November 25th. From her previous pregnancies she had made rapid recoveries. Her general condition on entering the hospital was good. The urine was normal.

The labor was normal, and for two days she seemed to do well, although she was thought to be somewhat hysterical.

On the third day she complained of a severe headache, and the temperature rose to 105.2° F. The lochia were normal, and there was only a slight tenderness of the abdomen.

On the fifth day the lochia became scanty and offensive, and remained so for a number of days. She was given intra-uterine injections daily for a week until the temperature became normal. The headache still persisted on the fifth day, and the patient was greatly depressed in spirits, claiming that she was going to die. On the following day she accused her attendants of attempting to poison her. When an effort was made to calm her she became greatly excited and reiterated her charges, referring everything which had been done for her to an attempt to kill her.

She was given bromide of potassium and chloral hydrate in large doses, but slept very little. She refused to take food, and was fed with great difficulty. The patient was transferred to a private room, and a constant watch provided. Only once did she show any violence, at this time striking at the nurse. She had delusions in many forms. She saw spirits and heard voices. Toward her child she was affectionate. There were short periods in which she seemed quite rational, but on being questioned she resumed her old charges.

Sixteen days after confinement her physical condition was excellent, and by persuasion she was taking an abundance of liquid food. It was still impossible to induce her to take solid food. An occasional cathartic kept the bowels in good condition. She gradually became quieter in her moods, but was still melancholy.

On the twenty-fourth day she seemed perfectly rational, and smiled when told of her accusations, of which she had no recollection. She complained of pressure about the head and a great desire to sleep. Her appetite gradually returned. She was still at times somewhat melancholy, and became petulant if asked about her condition.

On the thirty-third day after her confinement she sat up. She was discharged January 5th, forty-one days after confinement.

She steadily improved up to the time of her discharge. Her manner at that time was somewhat peculiar, but her friends stated that she had always been of a somewhat sombre disposition.

#### CASE II. SUBINVOLUTION.

M. C., twenty-three years old, was delivered of her first child December 9th.

Fourteen days later an examination, preparatory to her discharge from the hospital, was made. The cavity of the uterus was found to measure five inches. The patient was advised to remain in the hospital. She was put to bed, and given fluid extract of ergot, twenty minims every three hours, for five days. She was discharged from the hospital twenty-one days after delivery, the cavity of the uterus measuring three and seven eighths inches.

#### CASE III. SUBINVOLUTION.

K. C., twenty-nine years old, was examined fifteen days after the delivery of her third child.

The cavity of the uterus then measured four and three fourths inches. The patient was put to bed and given fluid extract of ergot, twenty minims every three hours, for five days. She was discharged twenty-six days after delivery, the uterus then measuring three and one half inches.

#### CASE IV. SECONDARY HÆMORRHAGE.

E. H., aged twenty-one years, after a normal labor gave birth to her first child December 5th. She convalesced well, and sat up on the ninth day. Five days later, while sitting in the ward, she was frightened by a patient who was in a hysterical convulsion. She jumped from her chair, and ran into her own room. Soon after she discovered a flow of blood, and called for assistance. When she was reached a large pool of blood was found upon the floor, and the blood was still flowing freely. The patient was blanched and fainting. She was immediately put to bed, and given one drachm fluid extract of ergot. The uterus was found enlarged, the fundus being three inches above the pubes. Constant pressure to the fundus was applied, and ice was used over the uterus and inside the vagina to induce contractions. The hæmorrhage continued, and a colpeurynter was inserted into the vagina. This checked the hæmorrhage. When removed, three hours later, a large clot was found in the vagina, but its removal was followed by no further hæmorrhage.

The patient was given twenty minims fluid extract ergot every three hours, beside stimulants and nourishing food. On the following day the uterus was washed out, and several clots removed. No loss of blood followed.

Three days after the first hæmorrhage there was a second one. It soon ceased without resort to other means than pressure over the fundus. The ergot was continued, and six days later the uterus was of normal size, and the patient sat up. There was no further hæmorrhage.

#### CASE V. CONGENITAL TEETH.

Two small white spots were accidentally noticed on the lower jaw of a child, then twelve days old. The spots were supposed to be thrush. Four days later the mother complained that the child caused her great pain in the nipples while nursing. An examination of the mother's breasts did not show adequate cause. On looking into the child's mouth the two spots were found to be two sharp-edged incisor teeth. They were removed, and appeared to be the right central and right lateral lower incisors.

#### CASE VI. PROLAPSE OF THE BLADDER.

J. M., aged thirty years, had previously given birth to six children. Although momentarily expecting to be confined she was obliged to keep at her work. After a hard day's washing she noticed something protruding from the vulva. On first examination a rounded mass was seen, which was thought to be the bag of the unruptured membranes. The patient was having pains with regular intervals.

The os admitted the finger, and through it could be felt the presenting head just above the pelvic brim. The membranes could be felt lying tightly over the head. The tumor took origin from the anterior wall of the vagina. It was a thick, fluctuating mass, projecting two inches beyond the labia, and as large as the fist. A catheter was inserted into the urethra, and passed directly downward into the tumor. Half a pint of urine was drawn off. By pressing back the head the bladder could be replaced, but showed a tendency to prolapse. The patient was admitted to the hospital, and perfect rest in bed required. This treatment was so effective that there was no return of the prolapse,

and she was delivered six days later after a normal labor.

#### CASE VII. ACUTE BRIGHT'S DISEASE.

Mrs. C. is twenty-one years old, and was delivered of her first child in December, 1880. During the latter weeks of pregnancy she had slight swelling of the feet and persistent vomiting, but the pregnancy was otherwise normal. The labor was normal, and the post-partum conditions were excellent.

The patient entered the hospital October 13, 1881. She was then pregnant for the second time, and her confinement was expected in a week or two. During this pregnancy she had been perfectly well until three weeks before entrance, when there appeared a swelling of the legs, and a noticeable diminution of the amount of urine. A diarrhoea set in about this time, which lasted throughout the pregnancy. A little later there was considerable dyspnoea and a slight cough, which was so persistent at times that it resulted in vomiting and retching. When the patient entered the hospital the feet, legs, and labia were greatly oedematous. The swelling extended to the buttocks and lower part of the abdomen. The face and hands were also at times puffy.

On examination of the chest a loud, mitral, systolic murmur could be heard. The lungs were normal.

During the first twenty-four hours of her stay in the hospital she secreted seventeen ounces of urine, containing eleven grammes of urea. The specific gravity was 1020; reaction neutral; albumen one per cent.; there was a large amount of sediment containing many pus corpuscles, granular, hyaline, and some epithelial casts.

The legs were elevated, and the patient was given *rr. ferri chlor.*, twenty drops three times a day, and also *potass. acetatis*, one half drachm three times a day. Under this treatment the swelling of the legs diminished, and the urine and urea were slightly increased. The patient became more comfortable. At times there was a slight headache, but there were no other cerebral symptoms.

Ten days after entrance the patient had a severe attack of dyspnoea and coughing. Nothing was raised by the cough, the mouth and throat being very dry. No râles were discovered in the lungs. The cough was not relieved by the ordinary remedies, and resulted in vomiting and retching. This continued until the patient became very much exhausted, and the pulse rose to 150. The dyspnoea was extreme. The patient was given nitrate of pilocarpine, one sixth grain, subcutaneously. It did not act vigorously, but produced slight salivation, and the patient soon became quiet. Three days later there was a second attack of dyspnoea, coughing, and retching. A frothy serum streaked with blood was raised by the cough. Coarse and fine râles could be heard in the lower part of the right chest. Pilocarpine, one sixth grain, was given as before. In fifteen minutes the skin became moist, and the patient was much relieved.

Fourteen days after her entrance the patient, after a normal labor of two hours' duration, gave birth to a male child, weighing six and one fourth pounds. After delivery she slept well for several hours. She was given *rr. digitalis*, ten minims three times a day, together with *rr. ferri chlor.* and *potass. acetatis*, as before.

On the following day the oedema was greatly dimin-

ished, and the cough was much better. The urine now began to increase rapidly, and on the third day it amounted to one hundred and forty-eight ounces. On the fourth day the feet and legs were of normal size.

The patient improved rapidly, and sat up on the tenth day. The urine was then normal in amount. An examination of the urine, seventeen days after delivery, showed the following characteristics: Specific gravity 1023; a trace of albumen; many pus and a few blood corpuscles.

The heart murmur was less marked, but was still plainly heard in front.

November 15th she left the hospital feeling strong and well, with no signs of oedema.

The following estimate of the daily amount of urea was made by Dr. Francis H. Williams:—

| Date.            | Urine in 24 Hours. | Urea in 24 Hours. |
|------------------|--------------------|-------------------|
| October 14 ..... | 16½                | 10.40 grm.        |
| October 15 ..... | 37                 | 23.53             |
| October 16 ..... | 24                 | 12.25             |
| October 17 ..... | 19                 | 14.10             |
| October 18 ..... | 17                 | 10.75             |
| October 19 ..... | 18½                | 10.68             |
| October 20 ..... | 23½                | 15.64             |
| October 21 ..... | 20½                | 16.00             |
| October 22 ..... | 29                 | 14.89             |
| October 23 ..... | 24½                | 14.45             |
| October 24 ..... | 21                 | 15.50             |
| October 25 ..... | 13                 | 11.00             |
| October 26 ..... | 16½                | 15.00             |
| October 27 ..... | 25½                | 16.60             |
| October 28 ..... | 49½                | 15.66             |
| October 29 ..... | 57                 | 20.00             |
| October 30 ..... | 148                | 22.50             |
| October 31 ..... | 104                | 15.00             |
| November 1 ..... | 50                 | 15.00             |
| November 2 ..... | 38                 | 19.4              |
| November 3 ..... | 48                 | 21.6              |
| November 4 ..... | 58                 | 18.7              |
| November 5 ..... | 56                 | 23.9              |

1 Child born.

— Dr. Adalbert Dacheck, professor of clinical medicine in the University of Vienna, died on March 24, at the age of fifty-seven. The cause of death was valvular disease of the heart, following acute rheumatism.

## Reports of Societies.

### PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

H. C. HAYEN, M. D., SECRETARY.

FEBRUARY 25, 1882. Sixty-five members present. DR. HODGES in the chair.

DR. WALTER CHANNING read a paper entitled

#### THE MENTAL STATE OF GITEAU.<sup>1</sup>

DR. FISHER, in opening the discussion, spoke as follows: It is a difficult subject to do justice to. I had Giteau under observation, at Washington, for two weeks, at the end of which time he was still a puzzle to me. He is undoubtedly of unsound mind. If he had not murdered the President almost any one would admit him to be mentally unsound, and to a certain extent crazy. The public feeling at Washington was so strong against him that it was difficult to free one's self from its influence. Again, one's feelings as a citizen rendered it difficult to render a calm and judicial opinion. The government experts seemed to me to feel the pressure of public opinion. I think if Giteau had had able counsel and had held his tongue he would have been declared insane. Most of the experts believed, before they saw him, in his delusion of inspiration; after personal observation they changed their mind. The hypothetical question put by the defense was meaningless and absurd. It was simply asking, "Is an insane man insane?" and did not elicit the experts' opinion as to Giteau's mental condition: this the defense did not try to do. The experts for the defense examined the prisoner carefully and frequently, and discussed the subject almost nightly. There were several theories, although all agreed that he was of unsound mind. The first was that he was an imbecile. His memory was so acute and his cunning so shrewd that this hypothesis seemed untenable. Another theory was that of primary insanity, that is, insanity existing from a very early age. There was no evidence of insanity, however, in the history of the first eighteen years of his life. Again, his exalted idea, his delusions, his conceit, suggested general paralysis of the insane, but the rational symptoms had existed fifteen or twenty years; and, moreover, the physical symptoms were absent. The theory of delusion being untenable it was difficult to formulate the insanity which all agreed to exist. Almost every alienist had seen people like Giteau, although of course he had certain individual peculiarities, for instance, Dr. George Washington Frost Mellen, who was for a long time an inmate of the South Boston Asylum.

There can be no doubt that Giteau was insane, but he knew his defense was false, and the experts for the defense knew it was false.

I think Giteau was honest in his belief that a number of prominent men thought well of him and were kindly disposed to him, and when he failed to get the Paris Consulship, I think he for the first time entertained an idea of revenge. The question of his legal responsibility is the important one. There are many who believe him insane, but responsible. The tests of the point used in the trial are, I think, antiquated. I believe, moreover, that no one physically insane should suffer the death penalty, but should be confined for life in an asylum for the criminal insane.

<sup>1</sup> Vide page 290 of this number of the JOURNAL.

DR. H. I. BOWDITCH thought that the idea of a sane man committing such an act was preposterous; the very fact not only argued but proved insanity, at the same time society had a right to defend itself against such monsters, but that does not necessitate hanging. The whole conduct of the trial had been a disgrace to the nation. Here was a man, a shiftless, insane person, from birth. Society must be protected, but Dr. Bowditch thought this could be equally well attained by life-long seclusion.

DR. BROUGHTON thought the experts occupied a too neutral ground. They should give a decided expression of opinion to the general profession, who could in this way only become qualified to properly form and lead public opinion.

DR. C. F. FOLSON, in reply, said that there was not enough existing evidence to justify a positive opinion. The case was particularly obscure. There was a great lack of testimony concerning the first eighteen years of his life. To determine what particular form of insanity is present it is often necessary to have a patient under observation for months continuously. That the man is to a certain extent insane all agree; beyond this the only way is to give the evidence on both sides, and let every one decide for himself. There is considerable evidence in favor of congenital insanity; again of so-called moral insanity, or of an acute disease eight to ten years ago with a recent exacerbation.

DR. E. W. CUSHING pointed out how greatly the popular opinion differed from that of the profession. The laity argue, — he must be hung. No sane man should be hung; therefore he must be insane. Society to-day is not capable of any other opinion. It needs to be evolutioned up to a higher grade before it can calmly discuss such a question of Giteau's responsibility.

DR. GOLDSMITH, by invitation, spoke as follows: I think Giteau is insane, that is, he inherited an incapacity for normal mental development. This did not appear until he was eighteen years old, on account of the lack of disturbing elements in his life. Later his environments were such that his mental weakness became apparent. His whole life was not that of a criminal; his petty acts of dishonesty were those of a fanatic, they were incidental to greater ends, which were not at all criminal. Giteau undoubtedly has a certain amount of responsibility; I do not believe in the divine pressure delusion. The trial shows the unsatisfactoriness of medical expert testimony, and of the legal criterion of insanity. The experts for the prosecution evaded the question of insanity, and stated in the strongest terms all the points that would imply insanity, while for the defense the hypothetical question was of no value. The difficulty is in deciding the question of responsibility. He is neither irresponsible or responsible, that is, he is responsible to a certain extent only. Society has an undoubted right to defend itself against such persons. In Massachusetts Giteau, if acquitted, could have been sent to an asylum for life. In the District where he was tried, I believe, this was not possible. It is very hard in such a case to reconcile humane feeling to the duty to society.

There is a pressing need for a change in regard to medical expert testimony and the legal criterion of insanity.

DR. LYMAN asked, if Giteau was not subject to the delusion of divine pressure, why was he not a proper subject for punishment.

DR. GOLDSMITH replied that although the delusion claimed by the defense did not exist, other delusions did, that is, that motives impelled him to the murder which would not have a sane man.

DR. REYNOLDS thought it fortunate that the nice questions of mental disease, interesting as they might be from a scientific standpoint, did not determine the action of society. If a man destroys everything that is dear society will take his life, and justly, too. This is a question not of abstract justice. Society cannot and will not make the allowance which an omniscient might and doubtless would. It owes a duty to itself and this it must and will perform, independent of our nice discriminations.

DR. CHANNING agreed with Dr. Reynolds as to the necessity for protection to society, but denied that this could only be accomplished by hanging. He claimed that deterrence might be gained without the death penalty, instancing the fact that when this was enforced in England for sheep-stealing the number of executions were greater than at present.

DR. FOLSON suggested that both Guiteau and his counsel had evidently studied the Poissett case. The term divine pressure being doubtless adopted from Freeman.

DR. C. W. WOOLDRIDGE reported

#### TWO CASES OF TRICHINOSIS.<sup>1</sup>

In reply to a question as to treatment he replied that it was purely expectant.

Adjourned.

### Recent Literature.

*The Science and Art of Midwifery.* By WILLIAM T. LUSK, A. M., M. D. New York: D. Appleton & Co. Pages 687.

The tardy appearance of a critical notice of Professor Lusk's contribution to obstetric literature must be ascribed to the excellence of the work. It was impossible to form a critical opinion of its merits without a careful reading, and, in fact, a re-reading, of the whole. The author has taken great pains to present to the profession the latest views held by recognized teachers on all the disputed points and the most approved methods of practice. The writer leans especially to the side of the German authorities, and recognizes the immense advantages which those practitioners possess, owing to their numerous opportunities for clinical observation and research.

We noted a few inaccuracies, which, however, will doubtless be corrected in a second edition, such, for example, as the statement, on page 82, that, the woman standing erect, the axis of the uterus forms with the horizon an angle of thirty-five degrees, while a few pages later (page 88) this angle is stated to be thirty degrees. We were astonished to find no allusion made to the use of the hydrate of chloral as an anæsthetic during labor, its advantages over both ether and chloroform being so great in many cases. In the chapter on operations for the induction of labor no reference whatever is made to manual dilatation, a method which certainly in many cases possesses advantages offered by no other plan of procedure. The book is, as a rule, admirably illustrated, and cannot fail to be at once

recognized as the best work on obstetrics (a term which we wish Professor Lusk had used instead of midwifery) in the English language.

*Opium Smoking.* By H. H. KANE, M. D., Author of *Drugs that Enslave.* New York: G. P. Putnam's Sons, 1882. 156 pages.

The work will be of service chiefly in calling attention to the existence and rapid growth of this habit among Americans. It is largely made up of quotations from various books and newspapers, and much of what is said in the last and longest chapter regarding the relations of England or India and China does not enhance the value of the book.

Very little is given about the treatment of this habit, for which the reader is referred to another of the author's publications.

*Recherches Cliniques et Anatomico-Pathologiques sur les Affections Cutanées d'Origine Nerveuse,* avec 4 planches en chromo-lithographie, etc. Par Henri Leloir. Paris: Published by the "Bureau" of the Progrès Médical.

After mentioning various clinical facts which suggest the nervous origin of certain cases of skin disease, and discussing their evincive value, the author describes the technique to be followed in making anatomical investigation of the condition of the nerves in such cases. He considers successively the different affections of the skin in which alteration of some part of the nervous system has been demonstrated by himself or by others, and then examines the various theories which have been proposed in order to explain the connection existing between morbid processes in the nerves and lesions in the skin. A few general remarks on the importance of the recognition of these cases, and on the treatment of the same, complete the book. No one will be disposed to deny the assertion of the author that some ("certain") cases of vitiligo, ichthyosis, ecchyma pemphigus, and cutaneous gangrene are caused by pathological changes in the nervous system, and an interesting collection of such cases is given.

The most prominent novelty in the book is the histological demonstration of pathological changes in the peripheral nerves in several instances of the above-mentioned diseases. These changes consist in a parenchymatous neuritis, resulting in atrophy of the axis cylinder, and final disappearance of the same, leaving the nerve sheaths empty. Such changes in the peripheral nerves may be primary and independent or secondary to lesions in the nervous centres, brain, cord, spinal nerve roots, and ganglia. In considering the pathogenesis of the subject, the author, after examining various hypotheses, is of the opinion that the lesions of the skin in such cases are due to interference with the trophic influence of the nerves upon the skin, a conveniently comprehensive term, verbal drapery serving to cloak the nakedness of ignorance. The nervous origin of these cases demands the assistance of electricity in their treatment. An excellent plan, and one deserving of more general adoption than it receives, is the one here followed of placing at the end of the book a short *resumé* of conclusions. The book is worth the attention of those interested in dermatology.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY, No. 4 PARK STREET, BOSTON, MASS.

## CHINOLIN TARTRATE.

UNDER the name of artificial quinia, medical literature, within a short time, has been made acquainted with a synthetically-prepared substance, known commercially as *chinolin* or *quinoline*, from the close resemblance in its chemical composition to the cinchona alkaloids; and, from a number of experiments made by independent observers, the therapeutic properties to a considerable extent bear out the resemblance still further. The physiological action of the tartrate of chinolin may be summed up as that of a decided apyretic and powerful antizymotic. Dr. Donath declares that it is superior in its antiseptic power to salicylic, boracic, and carbolic acids, or to copper sulphate and alcohol. In the proportion of 0.2 per cent. it arrests fermentation in milk and the development of bacteria; a 0.4 per cent. solution will prevent decomposition of blood or the curdling of milk. When administered internally it has not been found in the urine, and appears to be decomposed in the system. As a local antiseptic it has special advantages.

The ordinary commercial chinolin is a reddish-brown liquid, while the tartrate is a white crystalline powder. It often has a disgusting tobacco-like odor, due to some uncombined chinolin or to slow decomposition. Rueber<sup>1</sup> found that by repeated distillations of chinolin made synthetically according to Skraup's method (48 parts of *o*-benzole, 76 parts aniline, 240 parts of glycerin, and 200 of English sulphuric acid), he obtained a *colorless*, transparent, oily liquid which remained unchanged after six months, from which a specimen of fine acicular crystals of chinolin tartrate was obtained, which possessed only a faint odor. The salt was insoluble in ether, soluble in sixty-five parts of alcohol and in twenty parts of water at 15° C.; but water at 100° dissolves six times as great a proportion; the excess afterwards deposits on cooling. The author confirms the experience of Dr. Donath as to the value of this salt as an antiseptic, and asserts that it possesses no properties which would render it deleterious to health when used for the preservation of articles of food.

The tartrate of chinolin is said to have decided effect in periodical neuralgia and in intermittent fever, in doses of one or two grammes to adults, given in wafers or *cachets de pain*; it may be given to children in equal parts of syrup and distilled water. Pep-

permit is suggested as best adapted for disguising the taste. It does not cause any unpleasant after-effects, and has not thus far produced tinnitus or other cerebral disorder. If the claims made for this remedy find confirmation in further experience, it appears that it offers a promising substitute for the cinchona alkaloids, one which, with a large demand, can be manufactured and sold at a very small proportion of the price of quinia, and which in many cases will prove equally efficient. The literature of the subject is rapidly extending, and in a very short time the permanent value of chinolin tartrate will be known. Certainly no greater incentive to therapeutic research could be suggested than the possibility of obtaining an abundant supply of such an important addition to our materia medica as this is claimed to be. It is but fair to add that a partial trial of this agent at the Jewish Hospital in Philadelphia, while demonstrating that it possessed antiperiodic power, showed that its influence was less marked than that of quinia; but this may have been due to the fact that the dose of the latter has been more definitely settled.

## DR. BILLINGS'S ADDRESS TO A GRADUATING CLASS.

A CLEVER address was delivered two weeks ago by Dr. Billings, of Washington, to the graduating class of Bellevue Hospital Medical College. Wit and wisdom were very happily blended in it. The graduates who were fortunate enough to hear it will certainly not regard it as the least valuable part of their medical course, and though appealing to the attention of the duller or most careless fledgling the old practitioner will find in its perusal a sense of satisfaction and quiet enjoyment. Dr. Billings professes to have consulted previous to its delivery one hundred of the "greatest efforts" of his predecessors on previous occasions, but this seems to have buoyed up rather than swamped his humor and originality.

His hearers were congratulated on their prospects, and assured that—

"Our American life will present to you as much variety, as vivid contrasts, as subtle mysteries, and as many giants, demons, and sirens to be overcome or outwitted as any that the legends of old depict. No doubt you will soon come across some of that curious sect, the *antis*, who are beginning to make their appearance amongst us; antivaccinationists, antivivisectionists, anti-anything, so that it gives them an excuse to keep their names before the public. Taking them all in all, these *antis* are a curious class of cranks, worthy of careful study on the part of some of our experts in mental diseases during the brief intervals in which they have no medico-legal case on hand. Some of them are quite honest in their convictions, and all are very theological and emotional in their appeals, and to this they owe what success they have in achieving notoriety; and yet, while professing the most humane sentiments, they are unscrupulous even to cruelty in carrying out their fantastic ideas. They will not greet your coming on the stage of action with any particular enthusiasm, but you must not be discouraged on that account."

They were told to be prepared to encounter the manufacturing pharmacist, the canvasser, the publisher, the editor, the medical societies, the boards of health and registrars; to investigate preventive medicine, and not to fear that the sanitarian would make their

<sup>1</sup> Monthly Review of Medicine and Pharmacy, translated from Schweizerische Wochenschrift, No. 49.

services unnecessary, for the fool crop continues with unvarying regularity whatever may be the changes in other harvests; not to be in a hurry to write or teach.

Passing on to the code the speaker said:—

"The code—or perhaps I should now rather say the codes—of medical ethics are great mysteries to the public at large. By many it is supposed to be a sort of trades-union set of rules designed to protect the business interests of physicians, without any particular regard to the rest of the world. I need hardly say to you that this is not true. It may be summed up in this, that a physician should be a gentleman, and should treat other physicians and his patients as he would wish to be treated under like circumstances. And your duty in this manner is to attend to your own ethics and not those of other people. Medicine is not a rigid system of rules and formulae as it was in ancient Egypt; a fixed creed to which you are to subscribe, and from which you must not vary. It is a living, growing thing, making use of every resource which the progress of science brings; it is truly eclectic and catholic, testing all things, and holding fast to that which is good. It is not a system which forbids the use of any particular remedy, or limits its followers within the narrow bounds of any sect or ism. There are such systems, and there are a few men who advertise themselves as followers of such systems, and who really do follow them. There are also many men who so advertise, but who really do not follow them. Some of these last are well-educated physicians, but they are,—that is to say, from the point of view of a gentleman, they must be considered as,—in short, the more you know of their methods the more fervidly you will assent to what I have not said about them.' . . . Let us take a concrete example. You treat a case of pemphigus with arsenic. You may theorize as you like about the essential nature of pemphigus; you may select arsenic because you think it would produce the disease, or because you think it produces something contrary to the disease, or for no reason whatever beyond the empirical fact that you have seen a case of pemphigus recover under the use of arsenic. Also, you may give this arsenic alone or combined with other substances, and in any does that you please, from the decillionth of a grain to a grain, and you may explain the results as you like. But as an educated physician, and a gentleman, you may not advertise yourself as an arsenio-pemphigist, and denounce every one who does not adopt your theory and practice, and as there is a good deal of common-sense truth in the old adage, that a man may be known by the company he keeps, you will not have more to do than you can help with the men who do so advertise themselves; and still less will you have to do with those who advertise themselves as anti-arsenio-pemphigists, and then treat their cases with arsenic after all, and claim the results as due to dynamized brickdust.

Touching medical legislation the speaker said:—

"And please observe that this is all that you have to do. You are not to enter into controversies with them or about them, you are not to repine over their success or exult over their failures. They have another code of ethics from your own; that is all that need be said about it. Thus far I have been speaking of fairly educated sectarian physicians. As to the ordinary, uneducated, and bill-distributing quack, with his sure cure for cancer, or his pure vegetable specific for coughs, rheumatism, and dyspepsia, you may be sure that in the long run he will make rather more business for you than he takes away. Do not fall into the error of supposing that legislation can prevent the existence of this class of men, or that you need the protection of the law against them. The public interest demands such protection, if for no other reason than to secure a proper registration of the causes of death of all citizens, and it is not only your right, but your duty, to call the attention of legislators to these interests, but never seek protection on your own account."

In closing, Dr. Billings said to his hearers:—

"It is true that you are entering, nay, in your medical studies you have already entered, a world of labor, and pain, and sorrow. You will see how the destruction of the poor is their poverty, and how the sins of the fathers are visited upon the children; how neither culture, nor wealth, nor power, can forever put off the evil day; and how there is, at last, one event to all the sons of men.

"You must be prepared to deal with anxiety, fear, grief, and despair, as well as fever and physical pain; you are to be not only physician, but friend, confessor, guide, and judge, and you

cannot avoid these responsibilities if you would, nor should you if you could.

"Nevertheless, I can assure you that you are also entering a beautiful world, where the very shadows prove that plenty of sunshine exists, a world of brave men and good women, whose best and noblest characteristics are brought out most clearly and vividly in such scenes as those in which you will be called to act. But remember that, as a rule, you will find only what you seek and believe in."

We have made such extracts from this address, which was published in the *Medical News*, March 18th, as our limited space would permit, but they scarcely do justice to it, and we commend its perusal to those who may not have seen it.

## MEDICAL NOTES.

—The *British Medical Journal* of March 11th contains a short report from the Richmond Hospital, Surrey, of the case of a young man, who, while hurrying along in the dark, ran against an iron post, and "had his wind knocked out of him," and died collapsed twenty-two hours after the accident. "Post-mortem examination showed that the small intestine had been torn completely through twelve inches below the pylorus, where it crossed in front of the spine. This had apparently been caused by its being violently crushed between the iron post and the vertebral column. There was some bruising, and some slight hemorrhage into the cellular tissue in front of the spine. Only a few particles of the contents of the intestine had escaped into the peritoneum. It was interesting to notice about the rupture how the muscular coat of the intestine had retracted, allowing the loose mucous membrane to spread outside it for about half an inch, putting one in mind of the sleeve of a coat over which the shirt-cuff had been turned back. General peritonitis had already set in. The serous coats of the anterior coils of intestine were highly injected, and some of them were slightly adherent. All the other organs were uninjured. There were no external signs of injury."

This report gains an additional interest in connection with the experiments of Dr. Whitney published in the *JOURNAL* of July 21, 1881, by which it was shown that this eversion of the mucous membrane was a distinctive feature of ante-mortem lesions of the intestines, and served to distinguish them from post-mortem accidents.

—The antecedents of Roderick Edward Maclean, whose attempt upon the life of Her Majesty providentially failed, are, of course, undergoing investigation. According to the *British Medical Journal*, he is said to have taken up his temporary residence at Weston-super-Mare in 1880, from which place he was removed to the Somerset and Bath Lunatic Asylum, Wells. The medical officer who was at the time in charge of the male wards is not now at the asylum, but it has been thus far ascertained that Maclean, when admitted, had delusions of persecution, believed the world to be at enmity with him, and felt a strong impulse to kill some one. Two letters were written by him, a week before admission, to his sister, in

which he stated that he was determined to commit murder. He was admitted on June 2, 1880, and appears to have lost the above delusions in August. He is reported to have been well for some months before discharge, but his discharge was delayed, as he appeared to be destitute. He is said to have been of intemperate habits. He was finally discharged July 21, 1881. Those who worked with him state that he was rather weak-minded even when he appeared free from delusions; also, that he was fond of talking about the Queen and royal family, although he never gave expression to any desire to injure them.

— The celebrated anatomist Hyrtl was once busily engaged in dissecting in the anatomical rooms of the Vienna Hospital. A guard of military police came into the neighboring court upon which the windows of Hyrtl's rooms looked. They began to go through their evolutions, when Hyrtl threw open the window in a rage and cried out, "Withdraw, you slaves: disturb not with your fanfaronade the quiet of the dead." — *Med. Record.*

— In the *Practitioner* for February are some valuable suggestions as to nutrient suppositories. Artificially digested meat is mixed with a little wax and starch and made into a suppository. These suppositories are of such a size that the digested and extracted product of twenty ounces of meat from which the insoluble matter is removed is contained in about five suppositories. The convenience of this method is very great. It is easy for most patients to introduce them themselves; and their use is attended with no discomfort whatever in the majority of cases. After an hour or two the waxy basis is frequently returned, the pectone and extractive being absorbed. In some few cases, owing to irritability of the rectum, the whole suppository has returned; but this can be obviated by the addition of a little opium to each suppository. It is true that the amount of food administered in this way is very small, but every practitioner who has had cases of obstinate vomiting under his care knows how minute a quantity of nutriment will "keep body and soul together" for several weeks or months.

#### NEW YORK.

— At a meeting of the State Board of Charities, held March 16th, Dr. Stephen Smith and Mrs. C. R. Lowell presented a report in regard to the New York City asylums for the insane, in which it was shown that these institutions were greatly overcrowded and altogether without adequate hospital accommodation for the acutely insane. It had become imperative, the report went on to say, that the city should either enlarge its buildings or avail itself of the State accommodations for this class of cases. It was then stated that the Hudson River State Hospital, at Poughkeepsie, and the State Homœopathic Hospital, at Middletown, had spare room for three hundred patients, with all the facilities for the proper treatment of recent or acute cases. The board accordingly deemed it advisable that the matter should be laid before the New York Commissioners, with a request that they bring it to the attention of the proper city authorities.

— Miss Sarah Burr, who recently died in this city, left almost her entire fortune, consisting of three millions or more, to various charities. One of the bequests to the will provides for the founding of a new dispensary, and is as follows: "From the proceeds of my estate I give to my executors \$200,000, in trust, to receive the income and pay over the same half-yearly to the following-named persons, to be styled the Trustees of 'The Good Samaritan Dispensary,' in the city of New York, namely, to the persons who may at the time of payment hold the following offices, namely, that of the Governor of the New York Hospital, the President of the New York Dispensary, the President of the College of Physicians and Surgeons in the city of New York, the President of the New York Eye and Ear Infirmary, the President of the New York Institution for the Blind, the President and rector of St. Luke's Hospital, rector of St. Mark's Church, rector of Ascension Church, rector of the First Presbyterian Church, and my executors mentioned in my will, to be by them applied to the founding and support of a dispensary in the city of New York to be called 'The Good Samaritan Dispensary,' for the purpose of giving medical aid and advice to the indigent in the city of New York." Among the other medical institutions benefited by the will are the following: St. Luke's Hospital, \$30,000; Woman's Hospital, \$30,000; Home for Incurables, Northeastern Dispensary, Nursery and Child's Hospital, German Hospital, Mount Sinai Hospital, New York Infant Asylum, St. Mary's Hospital for Children, St. John's Guild, Floating Hospital, the Foundling Asylum, the New York Ophthalmic and Aural Institute, the Northern Dispensary, the Demilt Dispensary, the Manhattan Eye and Ear Hospital, the Northern Dispensary, and the Eastern Dispensary, each \$10,000.

#### Miscellany.

##### REPLY FROM DR. C. F. FOLSOM.

MR. EDITOR, — Until I had read the communications of Dr. Hamilton and Dr. Spitzka in the *JOURNAL*, March 9th and March 23d, I did not suppose that any one had inferred that I have a definite opinion as to the precise character of Guiteau's mental disease, although I consider him clearly insane. It seems to me that the available evidence, a part of which rests solely upon the statements of a tricky, untruthful man, is not yet sufficient to warrant an absolute diagnosis between congenital insanity (*primæ Verrücktheit*) and *folie raisonnante* developed at some time before the age of eighteen. Whether the "lawyer, theologian, and politician," can be said to be a monomaniac, in the common meaning of the word, and whether or not some later form of insanity has been added to his early or congenital disease, are points which, in my opinion, can only be decided by prolonged observations under somewhat favorable circumstances. As to general paralysis, I have only said that I am not sure that he has not that disease in an early stage. Many facts in the case seem to me to have been distorted, others exaggerated, and many repressed, to an extent which I regard

as unfortunate for the interests of exact science an legal precedent.

Very respectfully yours,

CHARLES F. FOLSOM.

Boston, March 24, 1882.

### ICE-WATER AND AMERICAN DYSPEPSIA.

MR. EDITOR.—On reading the editorial in the *Journal* for March 16th, on Ice-water, I am led to ask what proof there is of the oft-repeated assertion that dyspepsia is more prevalent in the United States than in Great Britain or other countries. Foreign medical writers certainly give the malady as much space in their books as ours do.

"G. A. S." in his echoes in the *London Illustrated News*, reprobrates the dreadful "American" habit of drinking a glass of ice-water before breakfast. "They all do it." What an awful constipated society he must have fallen into! S.

### LETTER FROM TANGIER.

MR. EDITOR.—The question is oftener asked of travelers and physicians than answered by them. "To what part of Europe shall I go to find a winter-climate at once dry and warm?"

England, Germany, and France are overhung during the winter months with fog, and liable to sudden changes of temperature. The Riviera is better, but not free from evening chill and dampness. Other places, where the climate is said to be delightful, as in Sicily and sunny Andalusia, are in some degree, though probably less than is generally believed, open to the objection that one cannot wander freely through the country unattended. A voyage up the Nile is outside the means and convenience of many patients.

Under these circumstances some of your readers may be glad to hear a few words on the climate and condition of life in Tangier, Morocco, of which I have had some three months' experience, and which possesses to a great degree some of the needful requirements. The air is dry, the weather equable and temperate, so that windows may generally be kept open day and night; there is no malaria; there is a good, home-like, and moderate-priced hotel, a good opportunity to study Eastern life, and a beautiful country which one can ride and walk over safely and at will. Furthermore, the place is easily reached, either by London and Gibraltar (five days' passage), or by a good French line of steamers from New York to Gibraltar direct.

Let me say, however, at the outset, that there is one feature about the climate which might render it unsuitable for persons unable to live most of the time out of doors. This is, namely, the liability to strong, continuous winds, which, although not usually cold, are nevertheless rather wearing, and interfere with the comfort of sitting still, except in sunny and sheltered spots. It is but fair to say, at the same time, that they have been far more constant this season than is usually the case.

This city, as the guide books will tell you, is picturesquely placed on the eastern slope of a low range of hills overlooking a broad and very beautiful bay, with the lovely and mountainous coast of Spain to its left, separated from it by the Straits of Gibraltar, which at that point are about twelve miles wide. It stands in constant communication with Gibraltar, which

is usually distinctly visible, though at a distance of thirty-two miles.

Inland, in every direction, stretches a fine rolling country made up of a succession of broad, level plains and high hills, bounded towards the east and southeast by higher hills, and eventually by a striking range of mountains, some of them snow-capped at the present moment, which end abruptly on the seashore in the Gibe-Monsa, one of the pillars of Hercules, which is close to the Spanish penal fortress of Ceuta, and directly opposite to Gibraltar. Eighteen miles south of Ceuta, and at the foot of this same range, lies Tetuan, a Moorish town of the same character with Tangier, but larger and richer. It can be reached from the latter place by a ride of forty miles, and well repays the trouble of a visit.

The hills, when not cultivated, are for the most part bare, or covered with a scrub growth of palmito, ilex, and many flowering shrubs, such as broom and heather. Both of the latter occur in several varieties, and grow to great height, as indeed does every plant that is found at all in this rich and favored country. The absence of forests might at first impress unfavorably the eye accustomed to our wooded landscapes, but one becomes soon strongly attached to these great plains and sharply-defined hills after seeing the remarkable contrasts and play of color which their clear-cut outlines and velvety sides, now largely green with sprouting crops, present. There are, moreover, enough trees, mainly olives, in occasional groups, to satisfy the artistic eye, and at a distance of ten or twelve miles are large cork forests.

The soil about Tangier is clayey, and under the sun becomes almost as hard as brick, but this does not cause the drainage of the town to be bad, because it possesses, for a wonder, a real system of underground sewerage. Furthermore, the principal hotel is placed outside the town itself, and raised well above it.

There are, to be sure, plenty of sources of superficial smells, which greet the nose plentifully in the narrow streets; still the abundant air prevents them from being unbearable. Certainly the city smells no worse, not as badly many say, as the Italian capitals.

Epidemic and endemic diseases are not common.

Plenty of pock-marked faces are indeed to be seen, but they are said to come mainly from the interior. At all events, vaccination is now very largely practiced, though not obligatory, in Tangier itself, and is gaining ground outside. The habit was introduced, it is said, by an Englishwoman, who some years ago became the favorite and favored wife of the Cherif. Every spring she still vaccinates gratis all comers with lymph obtained from England.

Let me define myself more exactly with regard to the important question of climate.

With regard to the dryness of the air I think there can be no dispute. Wet towels, oil-paints on canvas, and the like, dry with unusual rapidity; the stars are habitually as brilliant, perhaps more so, than with us on the clearest winter nights; and on a clear night I have even seen the outlines of Gibraltar, which is thirty-two miles away, with perfect distinctness, by the light of the moon. The horizon at sunset is usually unobscured by vapor, except along the coast of Spain, across the Straits, and usually in that direction also.

Upwards of thirty-seven inches of rain (this is the computation for Gibraltar) fall in the course of the year, and almost exclusively in the months from Octo-

ber to May. Still this happens usually in heavy showers at night; or, at long intervals, in rain storms of two or three days' duration, and habitually the sky is clear.

The temperature ranges, as a rule, between 50° and 60° (F.) in the twenty-four hours, with very exceptional falls to 45° F. or lower. Observations which I have made during the past ten days, with a registering thermometer, give the following results:—

| February. | Lowest<br>rang | Highest<br>Point during<br>Day. |   |
|-----------|----------------|---------------------------------|---|
| 9         | 47° F.         |                                 |   |
| 10        | 53             | 60 F.                           | Clear during day; Wind E.; rainy at night.              |
| 11        | 51             | 62                              | Showery; Wind S.W.; un-settled weather; rainy at night. |
| 12        | 43             | 60                              | Clearing weather; Wind N.W.                             |
| 13        | 48             | 63                              |   |
| 14        | 52.5           | 63                              |   |
| 15        | 52             | 59                              |   |
| 16        | 52             | 59                              | Clear; strong E. Wind                                   |
| 17        | 49             | 60                              |   |
| 18        | 50             | 59                              |   |
| 19        | 49             | 61                              | Clear; strong N. to N. E. Wind.                         |

The thermometer was in the shade, on the sill outside my window, which was always open.

These readings fail, however, to give a correct idea of the temperature as estimated by one's sense of comfort, for two reasons: on the one hand because the sun is so hot; on the other, because when the wind is blowing the air seems colder than is really the case.

The prevailing winds are east and west, of which the latter is light and pleasant, the former sometimes strong and relatively moist, though, in winter at least, thoroughly dry by most standards of comparison. Unless it is unusually severe it is easy to escape it by seeking a protected place, and a few miles inland it is but little felt.

It was with these facts in view that I said at the beginning of my letter that the climate was better suited for those who wished to lead an out-of-door life than for serious invalids. Very moderate exercise suffices to keep one perfectly warm; and when the wind is not blowing, or is kept off by the lay of the ground, the sun at once asserts itself, and the weather is like that of the best of our September days, warm yet never oppressive. Towards sunset the wind almost invariably dies away, and the evenings are delicious for strolling, though too cool for sitting still.

Even when the "Levanter" deposits a bank of fog over Gibraltar the air about Tangier is almost invariably clear.

With regard to the sources of interest and enjoyment which the place affords opinions would differ. For some there is nothing to do, the town is dirty, and the aspect of the country always the same; for others the weeks are but too short.

Certainly those who need libraries and clubs, and plenty of society, and who can see nothing but the superficial dirt, ignorance, and confusion in the habits and life of the Moors — to which one finds himself introduced perforce and without ceremony in the market-place and in the streets — will not care for Tangier. Artists must inevitably enjoy it. Thus Regnault came here for a short visit, but stayed two years, and only then went away, leaving his unfinished house and studio behind, because he felt himself called to fight against Germany.

The country seems to me extremely picturesque,

and as the Moors are a simple and friendly people, and live under the shadow — in this respect — of stringent laws, one may ride or walk, even to distant and lonely spots, without escort and without danger. Some travelers may tell a different story, but this is the universal testimony of all who are in a position to know the facts.

With the turbulent tribes of Oran and on the borders of Algiers the case is different; but in this neighborhood, although for long excursions in Tangier, as to Tetuan, it is obligatory to take a soldier along, his function is that of a passport, not a guard. It is undoubtedly to the influence of the foreign representatives, which is very great, especially that of the English, that this security is largely due; but as a matter of fact, if anything happens to a traveler in our neighborhood the Moorish government does not wait to look up the particular offender, but punishment is visited on the whole of the village to which he is supposed to belong, and so summary is the justice, so well recognized the *status quo*, that every one knows his best security lies in seeing that the peace is kept. This and nature seem to have made the people quiet and unoffending, and they are said to be particularly well disposed towards the English.

The hotel is small but good. There is good shooting (the close season begins in February), and hunts are organized at intervals by the English minister. Invalids who require much attendance would do well to bring a servant with them.

This is not the place to dilate upon the interest and picturesqueness attaching to the life of the Moor at Tangier. Suffice it to say that the scenes which are constantly before one's eyes are those of a rude civilization of centuries ago, which has come down to us almost unchanged, for the influence of the few Europeans who have settled here has made itself but little felt in that respect.

The invariable costume (except of the Jews, who are numerous and keep their own dress and customs) is the long flowing robe, with hood made of sheep's wool, which reaches to just below the knees.

The country people are apt to have the head and always the legs bare; the people of the city generally, or often, wear turbans and rich yellow undervests; the soldiers a pointed red Fez, and often a blue cloth burnous thrown over their white robes. The women, when one is allowed to see their faces, are often pretty when young, but when older are apt to have a dull, absent expression corresponding to their life of toil. The men are spare but muscular,<sup>1</sup> and have dignified, friendly faces.

As one looks down over the market-place filled with these shrouded, bare-legged figures in gray and brown, one group dignified and impassive, another gesticulating extravagantly; a dense ring here surrounding a snake-charmer, another, a little apart, listening to a storyteller; women and even young girls carrying huge bundles of wood, and may be a baby in addition,

<sup>1</sup> It is worth mentioning, by the way, that as every one goes bare-foot or wears only the well-known loose slippers, down at the heel, a better opportunity could hardly be offered for studying the unimpeded development of the foot, and I can aver that such a condition as the so-called "growing-out" of the metacarpophalangeal joint of the great toe, a production of the modern fashion in boots which is worthy of the Chinese, is absolutely unknown. The great toe of every adult, as of every child, is in a straight line with the inner margin of the foot, and sometimes even turns slightly inwards towards the middle line of the body, when the weight is thrown forward, so that a line drawn from the side of the heel to that of the toe would not touch the metacarpophalangeal joint.

strapped upon their backs; the slaughtering-place in plain view just to one side; a caravan of camels here, a lot of donkeys there (there is not a wheeled vehicle in the place), it is difficult to believe that when the eye is raised a little it will fall upon Gibraltar, the representative of civilized England.

In fact, those who have traveled further East say that the Eastern life, — the Mohammedan customs and character, — is scarcely anywhere to be seen, not in Cairo, nor in any easily accessible place, so unaffected by European civilization as at Tangier.

Yours truly, JAMES J. PUTNAM, M. D.

TANGIER, February 20, 1882.

## INSPECTION OF VACCINE FARMS.

[REPORTS OF DRs. ROSMER A. JOHNSON AND W. F. WHITNEY TO THE NATIONAL BOARD OF HEALTH.]

### *Dr. Johnson's Report.*

CHICAGO, February 13, 1882.

IN accordance with the instructions of the executive committee I visited, on the 12th instant, two of the vaccine establishments of the Northwestern Vaccine Company in the vicinity of Fond du Lac, Wisconsin, and the vaccine farm of Dr. E. L. Griffin.

The general direction of the Northwestern Vaccine Company is vested in Dr. J. G. Achenbach, of Fond du Lac. I called at his office four several times but failed to find him. At the first place visited, Seven-Mile Creek, the stock was poor, the stables cold and dirty, and the collecting room filthy. I saw no evidence of disease among the stock. No work was being done at the time of my visit. No cases were matured, and no new vaccinations practiced, for the reason, as I was told, that points could not be obtained. Mr. L. W. Russell, in charge, stated that the operations were carried on under the general direction of Dr. Achenbach, but that he gave no personal attention to vaccinating or collecting the virus. Mr. Russell did not claim to have any professional knowledge; simply followed instructions.

At Van Dyne, nine miles north of Fond du Lac, the Northwestern Vaccine Company has made arrangements with a German farmer to carry on the work of propagating virus. The stock is in good condition and the stables warm and clean. The operating room was also clean. Seven calves had been vaccinated a few days before my visit, but none were developed so as to enable me to judge of the character of the vesicles. The operations, both of vaccinating and collecting, were done by the farmer, whom I did not see. His wife said he had no knowledge of the business till last December, when Dr. Achenbach came out and gave him some instruction. The place is seldom visited by the doctor.

There are two other establishments in this neighborhood, — one about ten miles east of Fond du Lac, and the other, just going into operation, four miles south, — both owned and operated by the Northwestern Vaccine Company. So far as I could learn they do not differ materially from those noted above.

At Fox Lake, about twenty miles west, there is a vaccine farm conducted by two men who had formerly been employed in the business in Fond du Lac. I did not examine it.

The oldest vaccine establishment in Wisconsin, or so far as I know, in the Northwest, is that of Dr. E. L. Griffin, president of the Wisconsin State Board of Health. He has been engaged in the propagation of the virus for the last ten years. I found his stables and operating rooms scrupulously clean, his stock in good condition, and the doctor himself engaged in dipping the points in lymph from well-matured, typical vesicles. The demand upon him is greater than he can meet, and, as he will not trust the work to uneducated men, there has been a strong temptation for those who have only a meagre mechanical knowledge to engage in the business. The result of my visit has been to confirm my confidence in the professional knowledge and conscientious care of Dr. Griffin.

The diagnosis between pox and lymph is a matter of the utmost importance, and where so much is at stake the responsibility should not be left with those who are either ignorant or careless.

I regret that I failed to obtain a personal interview with the director of the Northwestern Vaccine Company. I have stated the facts as I saw them, or as I learned them from the employees.

Since my return to Chicago I have visited the vaccine stables of Dr. G. M. Dixon, located in the southern portion of this city. The work has been recently inaugurated, and it is hardly possible as yet to form a just opinion of its character. The place is clean, and the stock, so far as I could judge, healthy. Dr. Dixon was formerly engaged in the business in Fond du Lac, Wisconsin.

### *Dr. Whitney's Report.*

BOSTON, February 8, 1882.

IN compliance with instructions I visited the establishments for the production of vaccine virus, conducted by Dr. H. A. Martin & Son, in Brookline, and by the New England Vaccine Company, in Chelsea.

Dr. Martin occupies a large building originally erected for a private stable. This stands upon a sloping piece of ground, and thus affords room for a high basement, lighted from three sides. In it the animals are kept during the formation of the vesicles. Close by the stable is a long, narrow wooden structure, also used for the same purpose. The main floor of the building, originally the carriage and harness rooms, is occupied as an operating room. Here the animals are brought for inoculation, and it is here that the points are charged when the vesicles have matured.

The method of procedure in charging the points is as follows: The crusts which have formed over the patches are first removed, the patch is then squeezed between the blades of two pairs of long dressing or polypus forceps, and as soon as the lymph commences to ooze out the ivory points are charged with this on both sides. A patch has to be squeezed several times before it is exhausted, and it is impossible to prevent the admixture of a certain quantity of blood, as the clots which have formed in the small vessels of the granulation tissue are necessarily disturbed each time that the patch is squeezed. This gives to the dried film a slightly reddish-yellow look. The lymph thus obtained is quite thick, and coagulates so rapidly that the whole surface of the patch is covered by a jelly-like pellicle in a very few minutes. The points thus prepared are placed upon drying-boards, and are then sent to Roxbury, with the number of the animal attached to each lot, where they are arranged for distribution.

There is no doubt but that the place is overcrowded at present, owing to the great demand which exists. Thirty animals occupy the space that should accommodate about twenty, and this naturally leads to a little neglect of that absolute cleanliness which, if not essential, is desirable.

The daily average is estimated at from 5000 to 8000 points, each patch yielding from 100 to 200 points.

The New England Vaccine Company occupies three detached buildings in Chelsea: one for the inoculation of the animals and preparation of points, the other two for housing the animals.

The operating room is the ground floor of a two-storied wooden building. The animals are inoculated and allowed to stand in the operating room until the end of the day, when they are driven to a barn about three quarters of a mile distant, where they remain until the fifth day, when they are driven back to a stable near the operating room. This stable was very poorly ventilated, the animals were too crowded, and cleanliness was not rigorously attended to.

When the patches are ready the animal is transferred to the operating room. The crusts are then removed and the lymph allowed to exude spontaneously. The first which flows is slightly tinged with blood; this soon coagulates, and the lymph oozes out and collects as a clear, very slightly watery fluid, of a very light straw color, and easily coagulating. Into this the points are dipped on both sides. The film which is left when dry is perfectly clear and transparent.

The charged points, with the number of the animal, are carried directly to a room overhead, where they are allowed to dry and then arranged for distribution.

The average daily production is from 10,000 to 15,000 points, a single patch yielding from 250 to 500 points. The number of animals in stock varies between sixty and seventy.

The lymph thus furnished by these two establishments appears to be equally pure, and the comparative value will have to be established by practical tests.

The establishment of Messrs. Codman & Shurtleff, at Stoughton, was also visited.

At this the lymph is collected from the vesicles without using pressure and placed in small glass bottles, and the points are dipped in these. A mixture of the lymph from the various patches is thus obtained.

Much less attention was paid to the cleanliness of the premises than in the case of the other two establishments visited. The daily average is from 2000 to 5000 points.

## TREATMENT OF PERSISTENT VOMITING.

PROFESSOR CARL BRAUN, of Vienna, reports in a lecture the story of a visit to a remote part of the Austro-Hungarian Empire to render assistance to a patient in the first half of pregnancy supposed to be dying of uncontrollable vomiting. (*Wien. Med. Zeitung*, January 31st.) He found the patient in a very reduced condition, and the practitioner in attendance considered the induction of premature labor necessary, owing to the

persistence of the vomiting, and the consequent rapid loss of flesh. As, however, Professor Braun is no friend to the artificial induction of labor, he had the vaginal portion of the uterus bathed in a ten per cent. solution of nitrate of silver. After five minutes this was well dried, so that no further caustic action should take place. The result was so marked that in an hour the patient was able to partake of some roast veal, and after that no further vomiting took place.

## REPORTED MORTALITY FOR THE WEEK ENDING MARCH 18, 1882.

Deaths reported 2888 (no reports from New Orleans and Cleveland): 1149 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 642; consumption 435; lung diseases 428; diphtheria and croup 165; scarlet fever 141; small-pox 94; diarrheal diseases 45; whooping-cough 44; typhoid fever 43; measles 33; cerebro-spinal meningitis 21, erysipelas 20; malarial fevers 19; puerperal fever 16; typhus fever one. From *diarrheal diseases*, New York 18, St. Louis six, Chicago five, Baltimore three, Brooklyn three, Philadelphia, Buffalo, and Milwaukee two each, District of Columbia, Fall River, and Chelsea one each. From *whooping-cough*, New York 18, Boston eight, Brooklyn three, Philadelphia, Baltimore, Cincinnati, and Nashville two each, Chicago, District of Columbia, Pittsburgh, Providence, Lowell, Chelsea, and Taunton one each. From *typhoid fever*, Philadelphia 11, New York eight, Chicago five, Boston three, Brooklyn, Baltimore, Buffalo, Milwaukee, and Lowell two each, District of Columbia, Pittsburgh, Providence, Charleston, Nashville, and Cambridge one each. From *measles*, New York 15, Chicago eight, Brooklyn five, Philadelphia two, Boston, Baltimore, and Buffalo one each. From

*cerebro-spinal meningitis*, New York, Milwaukee, and Worcester three each, Chicago, St. Louis, Cincinnati, and Buffalo two each, Philadelphia, Pittsburgh, Lynn, and Somerville one each. From *erysipelas*, New York seven, Brooklyn three, Philadelphia, Chicago, Boston, Baltimore, Cincinnati, Pittsburgh, Buffalo, Lowell, Lynn, and Fitchburg one each. From *malarial fevers*, New York nine, St. Louis three, Baltimore two, Chicago, Cincinnati, Buffalo, Milwaukee, and Nashville one each. From *puerperal fever*, St. Louis six, Chicago four, New York, Brooklyn, Boston, Pittsburgh, Chelsea, and Spencer one each. From *typhus fever*, New York one.

One hundred and twenty-five cases of small-pox were reported in Cincinnati, Pittsburgh 44, St. Louis 15, Baltimore 12, District of Columbia 11, Milwaukee and Boston each three, Buffalo one; diphtheria 19 cases, typhoid fever seven, scarlet fever five in Boston; scarlet fever 18, and diphtheria four, in Milwaukee. In 36 cities and towns of Massachusetts, with a population of 993,104 (population of the State 1,783,086), the total death rate for the week was 19.27, against 19.34 and 20.37 for the previous two weeks.

For the week ending February 25th, in 173 German cities

and towns, with an estimated population of 8,466,078, the death rate was 27.9. Deaths reported 4541: under five 2232; pulmonary consumption 618, acute diseases of the respiratory organs 529, diphtheria and croup 235, diarrhoeal diseases 131, scarlet fever 86, whooping-cough 58, typhoid fever 54, measles 48, puerperal fever 25, small-pox (Tilsit, Nürnberg, Essen, seven, Eipen) 10, typhus fever (Königsberg, Elbing) two. The death-rates ranged from 16 in Potsdam to 45.9 in Essen; Königsberg 37.2; Breslau 31.1; Munich 40.1; Dresden 30.3; Berlin 24.8; Leipzig 22.7; Hamburg 29.2; Hanover 25.8; Bremen 23.3; Cologne 29.1; Frankfurt-on-Main 21.2; Strasbourg 37.5.

In the 28 English towns, with an estimated population of 8,455,320, for the week ending March 4th, the death-rate was 24.5. Deaths reported 371: acute diseases of the respiratory

organs (London) 470, whooping-cough 256, measles 154, scarlet fever 88, fever 49, diphtheria, 33, diarrhoea 30, small-pox (London 33) 28. The death-rates ranged from 19.4 in Hull to 38.2 in Blackburn; Birmingham 20.6; Leeds 22; Bristol 22.8; Sheffield 23; Linton 24; Manchester 28.7; Liverpool 29.5. In Edinburgh 20; Glasgow 34; Dublin 51.

For the week ending March 4th in the Swiss towns, population 479,934, there were 81 deaths from acute diseases of the respiratory organs, pulmonary consumption 52, diarrhoeal diseases 15, diphtheria and croup 12, whooping-cough nine, scarlet fever five, typhoid fever two. The death-rates were, Geneva 34.6; Zurich 54.1; Basle 21.2; Berne 40.2.

The meteorological record for the week ending March 18th, in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the U. S. Signal Corps:—

| Date.            | Barom-eter. | Thermom-eter. |          |          | Relative Humidity. |            |             | Direction of Wind. |            |            | Velocity of Wind. |            |            | State of Weather. <sup>1</sup> |            |            | Rainfall.   |                       |                   |

## A CASE OF ANGINA PECTORIS ASSOCIATED WITH ARTERIAL DISEASE AT THE BASE OF THE BRAIN. DEATH FROM ACUTE ANEMIA OF THE BRAIN.

BY WILLIAM HUNTER WORKMAN, M. D., WORCESTER, MASS.

The following case is that of a gentleman who recently died at the age of sixty-five years, having always led a life of mental activity, and whose health, up to the latter part of the year 1878, had usually been excellent. In December of that year, while walking in Paris, he was seized with symptoms of an alarming nature, for which he put himself under the care of Dr. C. E. Brown-Séquard, who in a letter thus describes what happened:—

"On December 12th Mr. —, being in his usual good state of health, was attacked with a great difficulty, almost an impossibility, of articulation. He states that his mind was then and remained perfectly clear. He had no paralysis, no involuntary movement, no pain anywhere. I saw him soon after, and ascertained that some impediment remained in his speech, and that the trouble was then and had been, when much worse some time before, only in the articulating power. There was no difficulty whatever in finding the proper word, so that there was no sign of aphasia. The patient was excited and moved, but not more so than any other person in presence of what may be considered a great danger of being stricken with paralysis or some other most serious affection. Three other much slighter attacks, and the last the slightest of all, occurred, one two days after the first, the second and third three days after the first. In these three last attacks nothing new took place, the only trouble being, as in the first, a mechanical impediment of speech."

These attacks, which were never repeated, were attended and followed by considerable mental depression and physical prostration, which after a while mostly passed away, and for the next two years the patient enjoyed a fair degree of health, though he could not endure as much fatigue as previously. For a few months after the illness in Paris the pulse was at times abnormally slow and intermittent. Returning to this country in February, 1879, he devoted himself to the care of his affairs and to literary pursuits with apparently unabated mental vigor.

During the last year of his life, however, his physical powers manifestly failed. He suffered with constipation and indigestion, moderate exertion wearied him, and mental excitement gave rise to a degree of prostration heretofore unknown. When tired or after excitement he was often troubled with restlessness, vertigo, and unpleasant sensations in the head, in consequence of which he became strongly impressed with the conviction that he would die of some affection of the brain. Still he took active exercise, walking or riding horseback daily, and was considered by his friends to be in good health.

In July, 1881, he had quite a severe attack of sciatica, lasting about a week, after which he did not recover his strength as rapidly as might have been expected, notwithstanding tonic treatment, and from this time he slowly lost flesh.

During the autumn the constipation and indigestion became more marked. Food remained a long time in the stomach undigested, and gas formed in large quantities,

producing a feeling of fullness. Remedies ordinarily efficacious in dyspepsia were employed without relief. The peristaltic movements of the stomach and bowels seemed obstinately sluggish. He also was affected with drowsiness, falling asleep while reading or engaged in conversation if there was a pause. This was very noticeable for three or four weeks preceding death.

Early in November last walking began to occasion paroxysms of distress or pain of a rather indefinite character. This pain was referred to the epigastrium and left hypochondrium, and was often so severe that he was obliged to stop to rest; after remaining quiet for a few minutes it would subside. Relief was also afforded by eructations of gas, which occurred freely near the close of these attacks. While the pain lasted he seemed much disturbed, his face being rather pale, and expression anxious, and on one or two occasions he said to his daughter, with whom he was walking, "I think these attacks will kill me." The pain frequently returned several times during a walk. It was never felt when he was quiet.

A careful physical examination a week before death revealed nothing abnormal in the sounds or action of the heart. The stomach was much distended, and palpation caused gas to escape freely from the mouth.

The attacks becoming more troublesome, and, indeed, occurring every time he took a walk, he was advised to desist entirely from walking, but this advice was not followed on the ground that want of exercise occasioned bad feelings in the head.

The day of his death he was unusually cheerful, active, and attentive to business. In the afternoon of January 17, 1882, as he was returning to his house, soon after he had reached the top of an ascending grade of some length, he suddenly dropped his cane, put his hand to his head, grasped the fence, and fell lifeless into the arms of a passer-by.

An autopsy was made by Drs. Everett, Moulton, and S. B. Woodward forty-three hours after death.

Heart of normal size. Right side filled with fluid blood. Left side contained small amount of fluid blood. No clots. Endocardium healthy, and valves also, except the free curtain of the mitral, upon which was a small atheromatous patch, which in no way impaired the action of the valve. Muscular substance was of good color, and apparently normal. Right coronary artery healthy except a small spot of atheroma at its commencement. Several small spots of the same in the wall of the left coronary artery. The calibre of these arteries was not perceptibly compromised. Small, recently formed atheromatous spots were found on the aortic wall just above semilunar valves.

Lungs, liver, kidneys, spleen, and stomach normal. Considerable undigested food in stomach.

Weight of brain fifty and one half ounces. Dura mater strongly adherent to the calvarium on either side of the longitudinal sinus. Vessels of cerebral pia mater contained but a small amount of blood. Sinuses and vessels at the base of the skull were entirely empty. There was notable anemia of the brain substance, the puncta cruenta being scarcely perceptible. No hemorrhage nor anything else abnormal in brain. Medulla oblongata and upper part of the spinal cord were very anemic, but otherwise apparently normal. The large arteries at the base of the brain were extensively and symmetrically atheromatous, their walls being in places five or six times thicker than the nor-

mal. The calibre of these arteries was distorted and compromised; that of both vertebrals at a distance of one inch from their junction was only one fourth the normal size; the inner coat of the internal carotids at their curve around the sella tursica and below in the carotid canal was converted into a pavement of calcareous plates. The entire tube of the basilar artery for a distance of seven eighths of an inch from the junction of vertebrals was much and uniformly thickened; the inferior cerebellar arteries at their origin were narrowed from one half to two thirds; the anterior and posterior spinals, as well as two branches of the basilar near the junction of the vertebrals, were reduced to mere threads, their lumina at their origin being scarcely perceptible to the eye; four of the transverse branches of the basilar were considerably narrowed; the posterior middle and anterior cerebrals were atheromatous, but their smaller branches were not diseased. The spinal cord was normal.

A microscopic examination of the heart substance showed the muscular fibrils to contain groups of brown pigment granules. There was no atrophy of the fibrils, and the transverse strie were distinctly visible; the walls of the arterioles and capillaries were normal.

The symptoms which developed about November 1, 1881, and gradually increased in frequency and severity until the fatal termination, lead me to ascribe the death of Mr. —, in a general way, to that clinically well-marked but pathologically complicated disease, *angina pectoris*.

In the light of the autopsy, however, a more definite idea may be formed as to the manner in which death occurred.

The most striking feature presented at the examination was the extreme anæmia of the brain, *medulla oblongata*, and upper part of the spinal cord, together with the absence of blood from the vessels within the cranium, particularly at the base. This condition must have appeared coincidently with or preceded death by a short space of time, and must have developed rapidly, as the patient met and recognized a man less than half a minute before he fell. It is unnecessary to cite here the evidence both of physiology and pathology to show that instant death is the result of cutting off the blood in any manner from the vital part of the *medulla oblongata*, in which the pneumogastric nerves have their origin. Granted this, and also the fact that in this case the blood supply was completely cut off from all parts of the brain, the conclusion follows that the immediate cause of death was a sudden and profound anæmia of the brain, or, more exactly, of the vital point at the base, whereby the function of the pneumogastric nerves was arrested and with it life.

But to go a step farther, the question arises, How was the anæmia induced? This leads to the consideration of the second marked pathological feature, which was the vascular disease at the base of the brain. As has been seen, the four large arteries supplying the brain with blood were converted by disease into rigid, irregular, greatly narrowed tubes, the greatest degree of narrowing being in the vertebrals. The branches of the latter and of the basilar distributed to the very seat of life were also so compromised that they could carry but little nutriment. Here, then, were found at the gateway of the brain two obstacles to the proper flow of the blood, namely, diminished calibre and greatly increased friction. To maintain the integrity of the intracranial circulation against these obstacles

the whole power of the heart must have been required, and disturbance of its action would be liable to be followed by symptoms of deficiency of blood in the brain, as was indeed often the case.

Under these circumstances any cause which would weaken or render irregular the action of the heart, such as exercise or pain, might easily induce fatal anæmia. It is not necessary to assume that the exciting cause should act with such power upon the heart as primarily to stop its beating, for it is evident that if its action were affected to the extent that it could not force the blood beyond the obstruction, a fatal result would ensue. Which of the above causes acted upon the heart just previous to death we have no means of determining. We know that the top of the hill had been reached, the ascent of which would naturally have had an effect upon the circulation. We also know that for about three months walking, especially up hill, had induced severe paroxysms of *angina*.

It is obvious that the arterial stenosis which contributed to the fatal result must have given rise for a long time to a condition of chronic anæmia, partial but ever increasing in degree. This manifested itself, when the patient had remained quiet for any length of time, in vague unpleasant sensations in the head. For relief from these he took regular active exercise, which in moderation had the desired effect, undoubtedly by stimulating the circulation. When, however, exercise or exertion was carried to the point of fatigue, and the balance of the circulation was disturbed thereby, or by mental excitement, more decided signs of insufficiency of blood in the brain appeared, such as pallor, vertigo, and actual cephalic distress, which passed away as soon as the equilibrium was restored. The uncontrollable drowsiness during the last few weeks of life was another evidence of the same condition.

Through the whole period of failing health the intellectual faculties remained unaffected. This may be accounted for by the fact that the carotids were not so much obstructed as the vertebrals, and the circulation through them was still adequate to the nutrition of the cerebral substance.

With the *medulla oblongata* and parts supplied by the vertebrals the case was different. The anæmia here was greater, the nervous tissue less perfectly nourished, and its functions impaired. This is shown by symptoms indicative of failing power in the nerves emanating from this tract.

The attacks in Paris pointed directly to some trouble with the fibres of origin of the spinal accessory and hypoglossal nerves. Just what then occurred it is not possible to determine. Probably there was some local interference with nutrition connected with the arterial disease, which even at that time must have made considerable progress to have caused such disturbance. Brown-Sequard thought that a temporary congestion took place. From the healthy appearance of the *medulla*, as well as from the transitory nature of the symptoms, it cannot be supposed that the attacks were due to thrombosis, embolism, or hæmorrhage.

Subsequently appeared symptoms similar in kind to those following section of the pneumogastric nerves, namely, constipation and enfeebled digestion, with torpid peristaltic movements of the stomach and intestines. These gradually increased in severity, not being much influenced by treatment, and were very marked for a few months previous to death, when the assimilative power failed and a decided loss of flesh was observable.

The action of the heart, which early in 1879 was slow and often irregular, later became normal in strength and rhythm, although easily affected by slight causes, as if the inhibitory power of the pneumogastric nerves was lessened and they could not respond to any additional demand upon them.

Finally, when the atheromatous process and consequent anæmia of the medulla oblongata had reached an extreme degree, came pain in the shape of paroxysms of angina pectoris. The angina manifested itself solely in the region of distribution of the pneumogastric nerves, pain never being complained of in the shoulder or arm, and occurred only while walking.

These facts, taken in connection with the practically healthy state of the heart, lungs, and abdominal organs, render it probable that the angina was due to lowered vitality, possibly to organic change in the medulla, expressing itself through the vagi, and was thus but the conclusion of a train of symptoms all pointing to the same nervous centre. The attacks would seem to have depended upon irritation of the sensory fibres of the pneumogastrics by the movements of the organs, particularly the distended stomach, in walking. Irritation here, as in the case of any other nerve whose vitality is lowered, reflexly produce pain. As the patient was never seen by a physician during the paroxysms, we know nothing of the effects upon the heart, but so far as any weakening of its action might have occurred this would probably be caused, if the above view be correct, reflexly through the depressor nerves; while the same, if occasioned by exercise without pain, would be likely to result from loss of the controlling influence of the inhibitory nerves.

Without attempting to argue at length upon the pathology of angina pectoris, it seems to the writer that this case is of value as supporting the view that the symptoms of this disease may be the manifestation of morbid action in or around the nervous centres, without the necessary implication of the heart or aorta.

## RECENT PROGRESS IN THEORY AND PRACTICE OF MEDICINE.<sup>1</sup>

BY GEORGE B. SHATTUCK, M. D.

### RHEUMATISM AND THE SALICYLIC TREATMENT.

THE recent appearance of a book<sup>2</sup> on Rheumatism and the Salicylic Treatment by Dr. MacLagan was the signal for the revival of a discussion of the merits of the treatment of rheumatism by salicin, salicylic acid, and the salicylates, in the London medical societies and medical journals.

MacLagan, in England, began to treat rheumatism with salicin in 1874, and his results were published in March, 1876;<sup>3</sup> Stricker and Riess, who in the mean time had been using in Germany salicylic acid manufactured from carbolic, published their experiences in January, 1876.<sup>4</sup> Since then the salicylic treatment has been through various stages of popularity, having been exalted by some to the place of a specific, and relegated by others to the company of its numerous unsatisfactory and uncertain predecessors.

A sufficiently long time has elapsed since the first introduction of this remedy to moderate the extreme enthusiasm following its early successes, and to give some just indications as to its administration, the class of cases to which it is adapted, and what may be fairly expected from it either of good or evil; and though, as MacLagan claims, the time may not be yet, and cannot for some years come, at which a satisfactory statistical statement of the results of the treatment can be compiled, the statistics presented, especially since the appearance of Dr. MacLagan's book, are sufficiently numerous, and some of them sufficiently homogeneous to be worth notice. It is easy to discredit statistics which do not support a theory, as it is to marshal others in favor of one, and the statistics which are likely to be given on such a subject we fear will never be altogether above reproach. Dr. MacLagan entertains a theory of the miasmatic origin of acute rheumatism, believing that its poison acts in a somewhat similar manner to that of malarial fever, and that the influence of the salicyl treatment upon it is akin to that of quinine in the other malady, and scarcely less reliable; in fact, he states that *a priori* reasoning as to the nature of the poison in acute rheumatism led him to use salicin; the use of which, he states, was not empirical nor was the theory the result rather than the cause of its exhibition. From the results claimed for the salicyl treatment in his own experience Dr. MacLagan is doubtless justified in classing it with other specifics, though they seem more than usually favorable as summed up in the following paragraph: "Treated thus, the course of uncomplicated acute rheumatism is arrested, the pain is abolished, and permanent convalescence begins frequently within twenty-four, and generally within forty-eight, hours of the time that treatment commences. In first attacks, and in young subjects, such is almost invariably the course of events when there is no cardiac complication." For Dr. M.'s method of administering the treatment to effect such results we refer readers to his book, page 199, though its main features may be stated as expressed by purity of the drug, an early commencement and sufficient continuance of treatment, full and frequently repeated doses. Dr. M. claims to be in possession of favorable figures concerning the treatment from thirty-nine different English hospitals.

The experience of others with the treatment in England we will summarize, as briefly as possible. Dr. P. W. Latham,<sup>5</sup> Professor of Medicine at Cambridge, from his experience in the hospital there, regards salicylic acid in a pure form and in a sufficient dose as much of a specific for acute rheumatism as quinine for ague.

Dr. Lewis Shapter,<sup>6</sup> physician to the Devon and Exeter Hospital, distinguishes between the arthritic and the pyretic manifestations of acute rheumatism, for the former he does not rely on the salicyl treatment, but finds it a useful weapon against the latter. He writes, concerning its claim to be regarded as a specific:—

"Now, in speaking of salicylic acid as a specific, is it contended that, in addition to the results following its marked antipyretic action, it has also an action peculiar to itself in controlling acute inflammation of sero-fibrous structures? or, in other words, is it curative of a condition which may be described as polyarthritic acuta? If salicylic acid is primarily an antipyretic

<sup>6</sup> British Medical Journal, vol. ii., page 1012, 1881.

ly, and the most powerful one we possess, then Niemeyer, in his observations on the use of quinia, appears to have prophetically shadowed forth the true position of salicylic acid. "Quinine is no more a specific in acute articular rheumatism than in pneumonia, typhus, and many other diseases in which it is nevertheless an important remedy. But it is one of the most powerful antipyretics, and it should be used when the fever is high. After the experiments of Weber and Billroth there can scarcely be any doubt that the quality of the blood in fever patients decidedly favors inflammatory disturbances of nutrition. If this be so, an antipyretic treatment has also an antiphlogistic action; and quinine, as well as other antipyretic remedies, would answer, not only the symptomatic indications, but also the indications from the disease, particularly in acute rheumatism, where, while the fever continues, new joints are continually becoming affected." Can we say any more than this of salicylic acid?

The views and experience of Dr. William Strunge<sup>1</sup> resemble more nearly those of MacLagan:—

"Now that salicin, and especially its compound, the salicylate of soda, are entitled to this high place in positive therapeutics I am quite convinced, and I think most hospital physicians will agree with me in that opinion. We give twenty grains, more or less, of the salicylate every three or four hours in a case of acute articular rheumatism; and in from three to five days, occasionally prolonged to nine, the temperature, which ranged from 103° F. to 106° F., falls to nearly or quite the normal point; whilst the pain and a great part of the swelling disappear at the same time. Quinine can do no more than this in ague, nor large doses of the iodide of potassium in syphilis, nor colchicum in gout.

"I have now treated over sixty cases of acute articular rheumatism in the infirmary here since salicin has come into use. In no case has there been any severely unpleasant result, nor long delay in deservescence and subsidence of pain and swelling. Careful watching is the chief thing required; and this is the reason that the remedy has gained so much greater repute in hospital than in private practice. Relapses will occur if the remedy be left off, or even reduced in quantity, too soon. In such a case full doses should be resumed immediately. There is, in most cases, great anæmia left to contend with, requiring iron as well as quinine for its cure. Without now entering into statistics, I can feel assured that the stay in hospital has been greatly less here under the treatment of the salicylates than under the potash or any other former mode of cure."

In a paper<sup>2</sup> read before the Medical Society of London Dr. Francis Warner, of the London Hospital, tabulates 190 cases treated with salicylate of soda and 79 cases without such treatment, and draws the following conclusions:—

Salicylic acid appears useful in lessening the duration of pyrexia. In 190 cases in which salicylic acid was employed the average duration of pyrexia was 5.5 days. In 79 cases without salicylin the average was 13.8 days.

Salicylic acid appears to lessen the duration of joint pain. In 277 cases in which salicin was used the average duration of pain was 5.3 days. In 67 cases without salicin the average was 9.3 days.

Salicin lessened the average of days of confinement

to bed. In 342 cases treated with salicin the average was 19.5 days. In 211 cases without salicin the average was 23.5 days.

Salicin lessened the average number of days in hospital. In 352 cases in which salicin was used the average stay in hospital was 34.9 days. In 387 cases without salicin the average was 36.2 days.

It appears, then, that salicin lessens the duration of the pyrexia and joint pain. Under the treatment by salicin the patient was able to get up sooner, and was kept in hospital a shorter time, than in cases otherwise treated.

The question then arises, Does salicin cure rheumatism? does it remove the rheumatic condition? We may take as proof of the presence of the rheumatic tendency the liability to the development of heart disease and the liability to relapses. In the salicin cases heart disease developed in 13.6 per cent; in cases treated otherwise, in 14.9 per cent. Relapses occurred in 33.6 per cent. of the salicin cases, on the average at the 15.2 day, lasting on the average 3.5 days,—that is, the rheumatic condition lasted till the 18.7 day, although fever and pain subsided much sooner under the treatment.

Another paper read at the London Medical Society gave an analysis by Dr. D. W. C. Hood<sup>3</sup> of 1200 cases of acute sthenic rheumatism at Guy's Hospital, occurring in patients under thirty-five years of age, treated by different physicians. From these cases a series of 350 is taken in which the salicylates were used, another series of 350 in which they were not used, and a third series of 500 in which they were not used. The number of 350 was chosen for the two first series for purposes of comparison with a series of that number of cases collected by Dr. Fagge<sup>4</sup> from the records of the same hospital. As the result of his experience and tables, Dr. Fagge declares himself strongly in favor of the salicylic treatment. He remarked that his hearers would, of course, see that he was a decided advocate of the treatment, and that before he had made the investigations presented he was strongly biased in its favor, but that he could honestly declare that his opinion had been forced upon him by his clinical experience. Indeed, when he first made trial of the drugs he was altogether skeptical as to their value, but when case after case occurred with scarcely a failure, he became satisfied that he had a most potent remedy in his hands. All further experience had strengthened this conviction in his mind, and he would now feel that he was accepting a very grave responsibility if he were to withhold a drug which he believed to be so useful from any patient placed under his care unless there were some good reason for doing so.

Dr. Hood concludes that a critical examination of his tables points out clearly and decidedly that patients taking salicylate lose their pains more quickly than those who do not take this remedy. "Out of Dr. Fagge's cases, of 350, 288 lost their pains within the first nine days of treatment; in my own series of 350 cases treated in a similar manner, 247 patients lost their pain in the same period of time; whereas of 350 cases treated without salicylates, only 141 lost pain within the nine days. Is the effect stable? Apparently not, for on looking at the tables we shall see that the relapses among patients taking the remedy are

<sup>1</sup> Ibid.

<sup>3</sup> London Lancet, vol. ii., 1119, 1881.

<sup>4</sup> London Lancet, vol. ii., 1030, 1881. London Medical Society, December 12, 1881.

vastly increased; and on further examining the average duration of stay in hospital, we find that patients taking this drug remain perceptibly longer under treatment. A scrutiny of my figures closely corroborates Dr. Fagge's statements that patients soon lose their pains, but are left feeble and exhausted after the use of this remedy.

"Endeavoring to estimate the effect of salicylate treatment upon cardiac complication I have divided my 1200 cases into three series again, — 350 without, 350 with salicylates, and the remaining 500 without. The construction of this table gave me no little difficulty, for, as Dr. Fagge justly observed, 'Much obscurity attaches itself to the interpretation of the cardiac murmurs heard during the course of acute rheumatism.' However, I have felt bound to enter all those cases in which the heart was noted as being affected at some period or other during the time the patient was under treatment. Do not understand by this that I have included cases in which the sounds were mentioned as being rough, prolonged, or the like, but those cases only in which a definite bruit existed. The presence of such bruit would in most cases be indorsed by the opinion of the physician in charge. We find that among the 350 patients treated by the salicylates 211 suffered from heart affection of some kind or other; among the 350 treated without salicylates 227 suffered from this complication; of the 500 without salicylates 273 were affected. The proportion between the two classes is much the same, but what little advantage there is does not appear to lie on the side of the salicylate treatment. With respect to the treatment of acute rheumatism, this complication of heart affection appears to me one of the most important points for consideration. Acute rheumatism is an expression the sum of which comprises known factors — to wit, pain, fever, often dangerously high, and a liability to mischief of heart. There are, doubtless, other points which, for the moment, lie without the scope of our present inquiry. But weigh these several factors one with the other; the preponderance of one is well-nigh overwhelming. Any remedy vaunted as a specific in acute rheumatism must show in marked degree its efficacy in controlling — I would rather say in preventing — heart disease. On this one count alone salicylate acid must be prepared to stand its trial, and must further submit to the most severe cross-examination at the hands of the profession."

At a previous meeting of the London Medical Society Dr. Isambard Owen<sup>1</sup> presented the statistics of 210 cases of acute and subacute rheumatism treated in St. George's Hospital in 1877 and 1878, showing in tabular form the comparative results of treatment. The cases fell into six sections, according to the treatment adopted in the primary attack: A, in 85 cases, salicylate of soda or ammonia, in initial doses, equivalent to three drachms or upwards per diem; B, in 52, salicylate, in initial doses equivalent to two drachms per diem; C, in 19, salicylate, in doses not exceeding one and one half drachms per diem; D, in 29, full doses of alkali, with or without quinine; E, in six, iodide of potassium; F, in the remaining 19, the mode of treatment was changed before the end of the primary attack. Sections A, B, and C were further subdivided according as the salicylate was combined with full doses of alkali or not. The cases in the first four sections were also classified according to their range of

temperature, and the presence or absence of marked redness and swelling about the joints.

Table I. showed the number of cases falling into each of the groups of this classification. The average duration of the attack previous to treatment, calculated for all the groups, was given, for the sake of clearness, only for the leading divisions, where it uniformly amounted to between seven and eight and one half days.

Table II. showed the average duration of pain, Table III. that of pyrexia, after the commencement of treatment, for all the groups. It appeared: (1) that the results bore no relation to the previous duration of the cases; (2) that the results were not affected by the character of the cases; (3) that practically similar numerical results were obtained from the use of salicylate, whether it were given at the onset in large, medium, or small doses; whether it were combined with alkali or prescribed alone; (4) that the results of salicylate treatment were in marked contrast to those of the alkaline treatment: three and one half, four, four and one half being the general averages of pain, three and one half, four, three and one half those of pyrexia, for Sections A, B, and C; while eight was the average of pain, and six and one half that of pyrexia for Section D.

It must be borne in mind that these numerical results give no account of the marked initial effects observed in many of the salicylate cases, especially those of Section A, as compared with the more uniform descent of pain and pyrexia in the cases treated with alkali; and also that in 23.5 per cent. of Section A, 13.5 per cent. of Section B, and 10.5 per cent. of Section C, the administration of the drug was embarrassed by toxic symptoms, a probably avoidable element in the future.

Table IV. showed the average residence in hospital after the commencement of treatment for each group. The results under this head were practically uniform for every system of treatment; the general averages for Sections A, B, C, and D being twenty-five, twenty-one, twenty-three, and twenty-six days respectively.

Tables VI. and VII. showed details of the cases between the end of the primary attack and the time of discharge. It appeared that *chronic rheumatism* persisted in two cases of Section A, with an aggregate of six days, in two of Section C, with an aggregate of fourteen days, and in two of Section D, with an aggregate of fifty-one days; that *relapses* occurred in twenty-seven per cent. of Section A, 26.9 per cent. of Section B, 36.8 per cent. of Section C, and 27.6 per cent. of Section D, with average durations of three and three fourths, four and three fourths, six, and two days respectively; that *relapses of a chronic character* occurred in two cases of Section A, and in one case of Section C, with aggregate durations of fifty-eight and two days respectively; and *relapses of a purely pyrexial character* in seven cases of Section A, with an average of seven days, and in one case in Section C, with a duration of five days.

By adding the aggregates of Tables VI. and VII. to those representing the duration of the primary attack (Table II.) the following results were obtained: —

Table VIII. *Average days of illness*, from the commencement of treatment, Section A, six days; Section B, six days; Section C, seven days; Section D, ten and one third days.

Section E comprised only cases possessing a special character.

<sup>1</sup> London Lancet, vol. ii., p. 1680, 1881.

Section F comprised: (1) one case not amenable to any form of treatment; (2) five cases in which salicylate of soda was superseded on account of toxic symptoms; (3) four in which salicylate was superseded for apparent failure, after five, six, two, and one day's trial respectively (no evident success attended the substituted treatment in any but the last of these); (4) one in which symptoms of diaphragmatic pleurisy appeared under salicylate, but rapidly lessened on substitution of alkali and quinine; (5) three cases in which salicylate was superseded while pain and fever were lessening; (6) three in which alkali was superseded by salicylate without apparent result; and (7) one in which bark was substituted for alkali before pain had ceased.

*Pericardial friction* appeared after admission in four cases of Section A, and in two of Section D. In all but one of these it was probable that cardiac complication existed before the commencement of treatment. The one excepted case was under treatment by full doses of salicylate of ammonia, without alkali.

*Permanent cardiac murmurs* appeared after admission in three cases under treatment A (in all but one with full doses of alkali), in one case under treatment C (with alkali), and in one under treatment D; *temporary murmurs* in two cases under treatment A (alkali given in one).

The urine in all cases was examined for albumen daily, if procurable, throughout the primary attack.

*Permanent albuminuria* was observed in four cases of section A, in one of Section B, and in one of Section C; but in none did it appear that it had originated after treatment.

*Temporary albuminuria* occurred in seventy-eight per cent. of the remaining cases of Section A, as against forty-three per cent. of those in Section D; or, excluding mere traces, in fifty-two per cent. against twenty-five per cent.

*Suppression of urine* for two days occurred in one case of Section A, and in one of Section F under alkali and quinine.

Among the toxic effects rashes are noticed in two cases, shivering in one. In one case (an alcoholic patient) the delirium took the form of delirium tremens.

Dr. De Havilland Hall,<sup>1</sup> at one of these meetings,<sup>2</sup> read statistics of fifty-five cases of acute rheumatism at the Westminster Hospital. Where the salicyl treatment was used, salicylate of soda was given, and when the symptoms were at all acute the patient was ordered it on admission. "The drug was given in doses of from ten to twenty grains, the usual treatment being fifteen or twenty grains every three or four hours. As the pain diminished and the temperature fell, the frequency of the dose was lessened to every six hours or three times a day. In some cases twenty grains were given every two hours till the pain abated, then an interval of no medicine, and a recourse to salicylates if the pains returned. This plan did not seem to answer, as relapses were more frequent than when the drug was gradually discontinued. The relapses, however, nearly always yielded at once to the salicylate.

"In contrasting the cases—thirty-eight in number—treated by the salicylate of soda, it will be noted that their average stay in hospital was less than a day in excess of the average stay of the sixteen cases treated without the salicylate, and that in comparing the days

of fever and pain the advantage is still more distinctly in favor of the salicylate plan.

"In comparing the heart complications which occurred nineteen times under observation, the proportion between the two sets of cases is practically the same; this speaks highly in favor of the salicylate plan of treatment, when the much more acute nature of cases subjected to this plan of treatment is borne in mind; but it is only what we should expect from the power the salicylate has of reducing the duration of the fever and of the pain.

"As regards other complications, there was no evidence to show that the salicylate exerted any injurious influence. Temporary albuminuria occurred three times, but only once in combination with salicinism, so that in all probability this was merely accidental. In none of the eight cases of salicinism was there any permanent effect left."

Dr. R. Douglas Powell,<sup>3</sup> of the Middlesex Hospital, in the course of this discussion, expressed himself as doubtful in regard to the value of hospital records upon a question like that of the salicyl treatment, as in a large number of the cases the attack is not a primary but a second or third attack, and a considerable number of the cases should be regarded as *separate attacks* rather than separate cases; this objection, however, scarcely applies to *comparative* effects of different forms of treatment.

Dr. T. Gilbert Smith,<sup>4</sup> of the London Hospital, presented tables of cases illustrating the frequency of cardiac complications in all cases of acute rheumatism before and since the introduction of the salicyl treatment, and other tables of primary attacks alone. His conclusions are stated as follows:—

"Table I. presents several classic series of cases treated in what may be termed the presalicylic era. Out of a total of 1727 cases, 940 were affected with heart disease of some kind, or 54.0 per cent. On withdrawing the cases whose figures suggest some error the percentage will be 56.0.

"Table II. tabulates cases treated at the hospitals named therein subsequent to the introduction of the salicyl compounds. Although all these cases here given were not treated by these remedies, yet the majority were, and in so large a number there is ample room for the beneficial influence of the drug to manifest itself if such influence exists. In this table it will be seen that out of 1748 cases 1109 presented heart complication, or 63.4 per cent. as against 54 per cent. (or 56.0) in the previous table.

"Table III. shows the amount of cardiac complication in cases of primary attacks of the disease, and here we should anticipate a lower percentage, for in such there is less likelihood of interference from previous cardiac lesion. According to Dr. Barclay, heart affection occurs 18 to 20 per cent. more frequently in subsequent than in primary attacks. Amongst the 246 cases recorded by Dr. Fuller, recent heart disease was found in 41.8 per cent. of first, and in 55.8 of subsequent, attacks. In this table, contrary to our expectations, in 384 cases out of 629 the heart was affected, or 60.5 per cent.

"Table IV. gives similar statistics of 533 cases treated by the salicyl compounds alone, and it also exhibits the highest percentage of cardiac complication, namely, 68.1.

<sup>1</sup> London Lancet, vol. ii., p. 1081, 1882.

<sup>2</sup> December 19, 1881.

<sup>3</sup> London Lancet, vol. i., p. 134, 1882.

<sup>4</sup> London Lancet, vol. i., pp. 136, 139, 1882.

"In comparing these statistics it may reasonably be presumed that whatever errors there may be (and doubtless there are many) in the method employed to determine the existence or not of cardiac disease, such errors are common to all, seeing that these figures represent in each series of cases numerous observers. The incomplete condition of the column showing the seat of the cardiac lesion explains the difficulty of obtaining such information, and exhibits the divergence of the interpretation of physical signs.

"From the consideration of these tables, therefore, I would say, in conclusion, that, notwithstanding our expectations based on the good effect of the salicyl compounds in several of the marked features of rheumatic fever, there is no evidence, so far as hospital statistics are concerned, to show that the introduction of the salicylate treatment has led to any diminution in the amount of cardiac complication in acute rheumatism."

In his concluding remarks at the final discussion of the subject at the meeting of the Society, January 16, 1882, the president, Dr. W. H. Broadbent,<sup>1</sup> of St. Mary's Hospital, said, in review of the preceding papers and remarks, —

"Now, however an individual might have been led away by preconceived notions, there is no reason why those who follow, and who look only at the results, should be so led away, and it is remarkable how the consensus of opinion tends in one direction; and I hold that the questions which I ventured to hope might receive some sort of answer by means of this discussion are really effectually answered, although, perhaps, no one has specially addressed himself to them. The answers may not have been direct, but they have been for that very reason all the more conclusive. I think we may say definitely that by means of salicylate compounds the duration of the pain and fever in rheumatism is unmistakably lessened, and, even if the stay in hospital is not materially shortened, certainly the suffering is very greatly diminished. With regard to relapses, perhaps we may say that they seem to be more common under the new than under the old methods of treatment, still I am quite sure that the explanation of this is to be found in the rapidity with which all the acute symptoms subside under the administration of salicylates. You cannot in these circumstances get the patients to be so careful of themselves as when they have gone through the terrible sufferings of an unrelieved attack of acute rheumatism. . . . I believe that when salicylates are brought to bear upon the fever in the first days of its existence we shall see a notable diminution in the heart disease, for in my own experience, during the whole administration of salicylates, it has been exceedingly rare to see heart disease spring up."

— Dr. Stephen Smith has been made commissioner of lunacy by Governor Cornell, of New York, in the place of Prof. John Ordronaux. The removal of the latter and appointment of Dr. Smith are rather severely criticized on the ground that while Dr. Ordronaux has devoted his lifetime to the study of mental diseases, and is an alienist of admitted authority, Dr. Smith, so far as is known, has never paid any special attention to the subject.

## Hospital Practice and Clinical Memoranda.

### CASE OF CHOREA, TREATED BY ARSENIC.<sup>2</sup>

BY F. MINOT, M. D.

MAUD B., a little girl nine years old, entered the Massachusetts General Hospital, April 20, 1881. Her father was in good health; the mother died of some disease of the uterus; her father's sister had chorea for a year. The child was of a nervous temperament, but had always been well. She had never had rheumatism. The present attack began March 15th, while the patient was at boarding-school, and the power of speech began to be lost April 1st. On her entrance into the hospital the child was unable to speak. On trying to walk she would fall down, and with difficulty could get up again. There was incessant incoördinate twitching of the legs, arms, and facial muscles. She could not feel herself, articles of food dropping from her hands. The movements were not more marked on one side than the other. During sleep the motions still persisted, though to a much less degree than while she was awake. She was not emaciated, nor especially anæmic. The intelligence was good. She readily understood what was said to her, though unable to reply.

There was no cardiac murmur. The appetite was good; bowels constipated. Two examinations of the urine showed the color to be pale; specific gravity 1015 and 1027; very slight trace of albumen, the urea at first diminished and then increased; sediment not abnormal.

The treatment consisted in suitable nourishment, exercise in the open air, and the solution of the arsenite of potash three times daily, beginning with three drops at a dose, which was gradually increased to seven drops, and then, on account of gastric disturbance, diminished to five drops. During the last week of her stay in the hospital she took, in addition, three grains of the citrate of iron and quinine before meals. Three days after taking the arsenic she became much more quiet during the night. April 26th (sixth day) she spoke for the first time. April 29th (ninth day) there was "marked improvement, in all respects." May 20th she was well, and ready for discharge, though she did not actually leave the hospital until the 30th. No exciting cause for the disease is known.

The total duration of this case was about fifty-six days; the time from the first dose of arsenic to recovery was twenty-nine days. If the remedy did not abridge the duration of the disease its beneficial effects were immediate and striking.

### ACUTE LOBULAR PLEURO-PNEUMONIA.<sup>2</sup>

BY G. M. GARLAND, M. D.,

Physician to the Eastern Dispensary.

THE following interesting cases were seen at the Boston Dispensary between October 1, 1881, and January 1, 1882. Each patient was stripped naked to the waist, and examined in the presence of a number of physicians and students, who were all agreed as to the symptoms enumerated below.

<sup>2</sup> Read before the Section for Clinical Medicine and Pathology of the Suffolk District Medical Society, March 9, 1882.

CASE I. Man, fifty-six years of age, feeble in appearance, poorly nourished, and with an anxious expression of face. He complained of a severe pain just below the left nipple, which had been preceded by a bad cough for two weeks; the pain was sufficient to interfere with his respiratory movements, caused him great suffering on coughing, and prevented sleep at night; there was no history of a chill; appetite was poor.

On examination the heart was found normal. The lungs were also normal, except as follows: At the lower edge of the fourth rib in the left mamillary line the percussion resonance became notably diminished in intensity, and an area of dullness extended from here downward to the bottom of the lung, and laterally as far as the anterior axillary line. On ausculting over this small area of dullness we obtained a boimful explosion of moist râles, which were mainly subcrepitant in character. It was very doubtful whether fine friction sounds were also audible. The dull area was very sensitive to touch.

The treatment consisted of an opiate cough mixture, and the application of a small blister directly over the most painful spot.

Three days later the patient returned to say that he was well. The stitch in the side vanished within twenty-four hours. His appetite returned, and he slept well. His cough had nearly disappeared. On examination we found that the resonance over the previously dull area was clear and full, and the râles were scanty, and more dry in character.

CASE II. Male, about forty years of age, married, works in an iron foundry, where he is exposed to great heat and currents of cold air. Family history good. Came to the Dispensary on December 12, 1881, with the following history: Took cold five weeks ago; after bad cough for four weeks was suddenly seized with pain under the left nipple; this pain grew worse until he was obliged to quit work; cannot take a long breath or cough without great suffering; cannot lie on the left side at all, and only with difficulty upon the right side; passes his nights in a half reclining posture by the kitchen fire; no history of a chill.

Patient had a distressed look in face; his breathing was costal in type, and superficial; there was a hard cough without expectoration; no appetite; bowels constipated.

Physical examination. The heart was normal in position. The left infra-mamillary region was very tender to pressure and to percussion. A dull area was found extending from the fourth intercostal space in the left mamillary line, downward to the bottom of the lung, and laterally as far as the left anterior axillary line. On auscultation we heard fine and medium moist râles all over the dull area. Nothing abnormal was detected in any other part of the lungs. Temperature 101° F.; pulse 80; respiration 28.

Treatment same as in Case I.

December 14, 1881. Patient reports himself better. He can take a long breath, and can lie down; his cough is less frequent and less dry; the left side is no longer tender to pressure.

On examination we found that the dullness had almost disappeared, and only an occasional moist râle could be heard below the nipple, with forced inspiration; there were also a few coarse mucous râles audible at the lower border of the left pectoral muscle in the anterior axillary line; temperature 100.1° F.; pulse 83,

Patient was not seen again until January 22, 1882, when the writer hunted him up at his home in South Boston. The physical signs over the region above described were then normal. He called himself well, except that he still coughed and raised considerable.

CASE III. Male, forty-two years of age, porter in a leather store; was never sick before; family history good. Entered Boston Dispensary November 9, 1881. Caught cold at a dance in August; this was followed by slight cough, which improved for a time. In September, however, it grew worse, and was very troublesome for about three weeks, when a stitch suddenly appeared under the left nipple; this stitch came on in the day time, about one week previous to his application for treatment; pain was continuous, prevented deep inspiration, and caused an anxious look in face; no history of chill.

On examination we found the same condition of things as described above. There was a dull area situated beneath the left nipple, and extending out to the left anterior axillary line; subcrepitant râles were numerous over this area; temperature 99.6° F.; pulse 104; respiration 24.

Treatment as in above cases.

November 12, 1881. Patient returned free from pain in the front of chest; he could breathe easily, and the cough was diminished; the infra-mamillary area of dullness had entirely disappeared, and only a few coarse râles were left; he complained, however, of a new pain at the very bottom of the left subscapular region.

He was not seen again until December 14, 1881, then said that he had worked steadily since the last examination, although he did not feel perfectly well. The resonance on the front of chest was normal; on auscultation an occasional high-pitched, sibilant râle and a few coarse mucous râles could be heard in the left infra-mamillary region on full inspiration; complained of some pain in the back of chest; temperature 98.8° F.; pulse 90.

February 27, 1882. Patient was again visited at his home, when the following new facts were obtained: About four weeks after our last visit patient began to cough severely again; this cough continued two weeks, when he was seized with severe pain in the left subscapular region. This kept him in bed for two days, and obliged him to call a neighboring physician. He was subsequently able to be dressed every day, but was very feeble and sick. He coughed and raised a great deal; sputa was white and yellow; no blood ever appeared; he was very short of breath; had no appetite; and emaciated rapidly. This state of things continued with slight improvement for four weeks, when, on examination, we found him very thin and weak. The left side was slightly collapsed, and moved much less than the right side during respiration; the heart impulse was about normal; the left back was very dull below the angle of the scapula, and this dullness extended to the side and front of the chest; the respiratory murmur was distinctly audible over the dull area, but was much diminished in intensity, as was also the vocal resonance; the vocal fremitus was barely perceptible; occasional râles could be heard; the upper part of the left lung and the entire right lung were perfectly normal so far as physical signs go.

The state of things thus found at this examination point almost indubitably to a recent attack of pleurisy, which had advanced to an almost complete absorp-

tion of the effusion, and a partial reëxpansion of the lung.

Case IV. Male, forty-four years old, baker; mother, three brothers, and three sisters died of consumption. Entered the Dispensary on November 15, 1881, with following complaints: Had coughed for two or three weeks, when he felt a stitch under the left nipple, two days before entrance; this stitch interfered with his breathing, and obliged him to give up work; appetite was good; tongue thinly coated; he favored the left side on removing his clothes.

On examination an area of dullness was found extending from the fourth rib in the left mammillary line downward to the bottom of the lung, and outward to the left anterior axillary line; over this area fine mucous râles were audible; temperature 100.4° F.; pulse 112; respiration 24.

Treatment as in other cases.

November 17th. Patient returned without improvement. The left side was then less mobile than the right one; it was tender to the touch in the subscapular region, and on examination we found evidence of a beginning pleuritic effusion; temperature 100.2° F.; pulse 105; respiration 23.

November 23d. Reports himself as feeling better, but fast walking takes away his breath; has very little pain except a slight amount in his left groin; the physical signs showed the usual evidence of a pleuritic effusion, which reached as high as the fourth rib in front and the angle of the scapula behind; the heart was carried to the right; temperature 99.6° F.; pulse 95; respiration 28.

December 5th. Patient again returned to report progress. He then complained of tightness across his back, and inability to hold his water; said that he had resumed his work, and although the effusion was undiminished in size he was unwilling to submit to any operation for its removal, because he did not wish to give up work.

These cases are identical in the manner of their development. Beginning with a somewhat violent cold, each patient, after a few weeks of coughing, was suddenly seized with a severe pain below the left nipple, which was continuous in character, interfered with breathing and sleeping, and produced a strikingly anxious expression in the face. Combined with the pain were loss of appetite, physical prostration, acceleration of the pulse, and an elevation of the bodily temperature, 99.6° F. to 101° F. There was no initial chill in any case. The cough was dry and hard, and caused much suffering.

On physical examination we discovered another striking point of resemblance, namely, an area of dullness similar in position and extent in each patient. From the lower edge of the fourth rib in the left mammillary line the pulmonary resonance was diminished downward to the bottom of the lung, and outward as far as the left anterior axillary. The axillary regions and all other parts of the lung in each case were normal. Over the dull area we heard fine and medium mucous râles with both phases of respiration.

The diagnosis lay between localized capillary bronchitis, atelectasis of the lung, acute lobular pneumonia, and pleurisy. While capillary bronchitis was seemingly present, as shown by the subcrepitant râles, yet the dullness would indicate some trouble still deeper than the bronchial tubes. We are not prepared to deny the possible collapse of the lung, yet the acute-

ness of the inflammatory process as shown by the elevated temperature, the stitch in the side, and the tenderness on pressure, leads us to believe that we had acute lobular pleuro-pneumonia. In Cases I, II, and III, the pain, and probably the pulmonary complication, had existed about a week prior to the first visit. In each of these cases the symptoms began to subside in the next twenty-four hours, and at the end of three days the patients were well so far as their subjective feelings and the infra-mammillary physical signs were concerned. In the fourth case the pain had existed only two days when the patient was first seen, and the symptoms did not improve as in the previous cases. The pleuritic complication rapidly became more prominent until we soon had a copious pleuritic effusion to deal with.

In regard to the sequelæ of these cases, we found Case II, still suffering from severe cough several weeks after the first attack. Patient III improved slowly for five or six weeks, when he was again seized with pain, and has since apparently passed through an ordinary attack of pleurisy with effusion.

## UNINTENTIONAL ASPIRATION OF THE LIVER.

BY FREDERICK C. SHATTUCK, M. D.

E. H. G., a vigorous young man of twenty, and of good family history, was admitted to the Massachusetts General Hospital November 15, 1881. For the last three months his work had involved standing in the doorway of the ice chamber of a large slaughter house, and he reported that for four weeks previous to entrance to hospital he had suffered from gradually increasing cough, with considerable expectoration, at times green and thick, at times white and frothy.

November 16th. Physical examination of the chest gave nearly negative results, the respiration at both bases being rather feeble, with a few râles. Severe pain in the right side soon came on however, and three days later, November 19th, there were well-marked signs of effusions in the right pleural sac and probable signs of pneumonia of the right lower lobe or lobes. The effusion increased gradually, the apex of the heart moved somewhat outside of the left nipple, but there was nothing in the patient's condition which caused anxiety.

December 1st. Fætor of the breath and expectoration were first noted.

December 2d. About twelve ounces of thin, semi-opaque sputa were raised.

December 3d. The dyspnoea was so severe that I decided to tap him, being in charge of the service during the temporary absence of the visiting physician, Dr. Shattuck. In order to save the patient the fatigue of sitting up I chose the anterior axillary line for puncture, but from not counting the ribs carefully inserted the needle lower than I should have done, in the seventh intercostal space. About two ounces of apparently clear blood were withdrawn, and the needle was removed soon after, no more fluid being obtained and the patient complaining of pain. The next morning I punctured again, but below the angle of the scapula, and this time obtained about twenty ounces of very fetid pus.

<sup>1</sup> Read before the Section for Clinical Medicine and Pathology of the Suffolk District Medical Society, March 9, 1882.

A few days later a free incision was made by Dr. A. T. Cabot in the sixth interspace and anterior axillary line under strict antiseptic precautions, giving exit to a large amount of most offensive pus and a couple of shreds of tissue, one of which was examined microscopically but no elastic fibres were found.

The operation gave great relief to the patient, who made a gradual recovery, and was discharged from the hospital March 8th in very good condition. The right lung is still much disabled by false membranes, but there is every reason to think that, with time, the patient will be practically well.

The point to which I wish to draw especial attention is the puncture of the liver without, as far as can be seen, any evil consequences. The aspirator has now been so long in use that we have learned how safely a small needle or trocar can be plunged into almost any organ or part of the body; and the liver has been punctured many times, unintentionally as well as intentionally, before this. A peculiarity of this case is that the point of the needle must have lain free in a large hepatic vessel, inasmuch as a considerable quantity of blood flowed freely into the receiver without any unusual force being applied to the piston. Ordinarily if a healthy liver is tapped nothing at all, or, at most, a few drops of blood, will be obtained, and it was not until the second and successful attempt had been made to reach the pleural cavity that I was entirely convinced as to the precise nature of my mistake. This is the only case which I recall in which I have tapped in the axillary space, it being my rule to insert the needle in the back; and should it seem desirable to choose the axillary space again I should not puncture at a point lower than the fifth intercostal space, unless the effusion were a very large one and had caused marked displacement of the liver.

My sincere thanks are due to Drs. Shattuck, A. T. Cabot, and Abbot, who kindly placed the whole records of the case at my disposal.

#### A CASE OF INTUSSUSCEPTION.\*

BY T. M. BOTCH, M. D.

A MALE infant six months old, breast fed and previously perfectly healthy, after showing a loss of appetite for several days, began to have abdominal pain on the morning of August 30th, and at half past twelve had a discharge of blood from the rectum, apparently unminged with faecal matter or mucus. The bowels had been moved regularly on the previous day, and there had been no tendency to constipation.

After taking a few drops of ginger at half past one he vomited. During the afternoon he had five or six bloody discharges and did not retain an enema of starch and laudanum which was given.

I saw the infant in the evening and found him looking well, but having from time to time slight attacks of abdominal pain and showing an indisposition to nurse. The temperature was 39.4° C. An examination of the abdomen revealed nothing abnormal.

August 31st. The infant was reported to have had a restless night, to have vomited several times after nursing and to have had six discharges of blood. Temperature 38.2° C.; pulse 135, of good character;

general appearance good. Abdomen soft and not tender on pressure, but between the umbilicus and the left costal cartilages a rather undefined cylindrical tumor could be detected. At four p. m., Dr. Langmaid saw the patient with me in consultation, and at that time no tumor was detected and the infant looked and nursed well. The bloody discharges, however, had not ceased, though they were less frequent and the starch and laudanum enemata were therefore continued and were retained.

September 1st. The patient was reported to have had a restless night and to have cried out a good deal with pain. Dr. Minot saw the case in consultation with me at eleven a. m. Rectal examination revealed no obstruction but brought away a large jelly-like mass supposed to be bloody mucus, and reported by Dr. Gannett, who afterwards examined it, to probably contain portions of the mucous membrane of the intestine in a condition of fatty and albuminoid degeneration, such as would be expected where the nutrition of a portion of the intestine was cut off. On examination of the abdomen, the same cylindrical tumor was felt as at my second examination, but much more defined and unmistakable.

Ether was given and hydrostatic pressure on the rectum at a height of about 180 cm. was made with the buttocks raised, and by means of a fountain syringe and the rubber bulb described by Dr. Putnam in the successful case reported by him in the *BOSTON MEDICAL AND SURGICAL JOURNAL*, April 21, 1881. The pressure was kept up for about ten minutes without producing the slightest effect on the tumor.

During the afternoon the infant came out of his ether well; he took a little breast milk, looked pretty well; temperature 38.2° C.; pulse of good character; no more vomiting or bloody discharges.

It was decided to wait until the following morning before resorting to abdominal section. During the night the child became restless and died suddenly at 11 p. m.

September 2d, eight a. m. Dr. Haven performed the autopsy, the result of which can be seen in this portion of the intestine, which was kept for examination.

Nothing abnormal was discovered in the thorax or abdomen, excepting an ileo-caecal intussusception.

Hydrostatic pressure was again tried with the same apparatus used during life, but at a height of about 250 cm. No effect was produced on the invagination, and on examining the specimen you will see that even if no adhesions had taken place, the twisted position of the retained caecum would have effectually prevented its being pushed back by water in the colon.

A certain degree of anxiety is usually felt by those who have made use of hydrostatic pressure in these cases regarding the danger of bursting the intestine, and in order to test the amount of pressure which the intestine can withstand, the abdomen of an infant's cadaver was laid open and the nozzle of a syringe firmly fastened in the rectum. A ligature was then passed around the large intestine just below the ileo-caecal valve. With a pressure of 180 cm. in height, transudation took place; with a pressure of 268 cm. the intestine burst, the rent occurring 35 cm. from the anus. The length from the anus to the ileo-caecal valve was 75 cm.

It was also found by another experiment that a pressure of only 12 to 30 cm. was necessary to force the water through the ileo-caecal valve and that it then soon escaped through the stomach and throat.

\* Read before the Section for Clinical Medicine and Pathology of the Suffolk District Medical Society, March 9, 1882.

Taking these experiments, then, for what they are worth, we probably need not fear to use a pressure of from 230 to 260 cm. (8-9 feet) in treating these acute cases of intussusception, where the intestine is apparently otherwise healthy.

Dr. Whitney has carefully prepared the specimen, but has not until now attempted to fully reduce the invagination and thus determine whether abdominal section would have been of any avail.

### A CASE OF LOBULAR PNEUMONIA.<sup>1</sup>

BY T. M. ROTCH, M. D.

THE following case is reported as one of lobular pneumonia, the physical signs in the lungs being the most prominent feature of the attack, and, in connection with the severity of the constitutional symptoms, making the fact of the patient's complete recovery of unusual interest clinically. A woman, aged thirty years, unmarried, and always delicate, after complaining of loss of appetite and weakness for six or seven days, and with a history of exposure to cold while sweeping, was seized December 16, 1879, with vomiting, epigastric tenderness, and headache, and was found to have a pulse of 120 and a temperature of 101° F. I saw the case with Dr. Charles Williams, and a physical examination showed the lungs and heart to be normal. The vomiting ceased on the 18th, but the pulse continued to average from 120 to 130, and the temperature, both morning and evening, to be 104° F. This state of affairs continued until the evening of the 22d, when an examination of the lungs showed for the first time a variation from the normal, consisting of harsh respiration and a slight degree of circumscribed dullness over a portion of the right lower lobe behind, just below and to the left of the scapula.

December 23d. Coarse moist râles were heard over the dull region and there was cough and a moderate amount of sputa consisting of thick yellow mucus, with a slight amount of bright red blood at times.

December 24th. Harsh respiration was heard over the left lung also, but the râles and dullness were still confined to the area about two inches in diameter, first noticed in the right lung. Temperature 103.5° F.; pulse 160; respiration 50.

December 25th. The dullness had disappeared from the right lung, though the circumscribed moist râles remained; two or three small circumscribed areas of moist râles were also found in the back of the left lung, and a slight degree of dullness over one of these areas.

December 27th. A few circumscribed areas of dullness and moist râles over right front.

December 28th. No râles or dullness over right front,—the râles were finer in right back. Over the left back the dullness and râles were confined to an area about three inches in diameter below and a little to the right of the scapula, and in this region there was bronchial respiration. The blood had disappeared from the sputa; there was no enlargement of the spleen or tenderness of the abdomen, and the bowels were constipated.

December 29th. Good resonance over both fronts

and a few sibilants and sonorous râles; râles as before in both backs.

December 30th. Slightly delirious; coughed more and sputa contained streaks of blood. Physical examination as before.

January 3d. Has been growing weaker and picks at bedclothes. The pulse and respirations have remained the same, the temperature about 100° F.; has been so weak that no physical examination could be made.

January 5th. Takes food more willingly and looks better, but is still completely prostrated; the delirium has passed off.

January 7th. An examination of the lungs showed good resonance and no râles over both fronts and backs; the respiration was still, however, rather harsh.

January 12th. Has been steadily gaining in appetite and strength. Pulse 120; respiration 28; temperature 99.8° F. Less cough.

From this time until January 26th the temperature, pulse, and respiration remained the same. At one time a circumscribed area of dullness and râles was again found in the right back, and an abdominal abscess formed, which had to be opened. By January 29th, however, the patient was sitting up, the abscess had discharged and closed, the lungs were found to be normal and the temperature 98.8°; respiration 32; pulse 116. The patient was sent to the country and gained steadily in appetite, weight, and strength. Since her recovery she has been well and strong, and an examination made March 2, 1882, showed the lungs, pulse, respiration, and temperature to be perfectly normal. The treatment consisted of large doses of brandy and quinine.

##### SECTION FOR CLINICAL MEDICINE AND PATHOLOGY.

ALBERT N. BLODGETT, M. D., SECRETARY.

MARCH 9, 1882. Meeting called to order at 8.15, Dr. G. B. SHATTUCK, presiding.

Dr. F. MINOT presented a paper entitled

##### A CASE OF CHOREA TREATED BY ARSENIC.<sup>1</sup>

Dr. BOWDITCH said that it certainly seemed that the arsenic had a decided effect, but it was a question if the changed surroundings of the patient, from her previous residence, to the hospital might not have had some influence upon the disease.

Dr. MINOT replied that the child was at a boarding-school, and came from a good home. In the hospital she was, nevertheless, the subject of special care, being in a separate room. The effect of treatment was marked and immediate in respect to the violence of the movements. The disease undoubtedly ran its normal course, but the severity was modified. Arsenic and quinia are known to have a decided effect in chorea. The duration of the disease was fifty-six days; the duration of treatment was twenty-nine days, when the patient was well. The child had never had rheumatism and there was no cardiac murmur.

Dr. BOWDITCH asked if the medicine would have had the effect observed in her treatment at the hospital if administered while the child was still at school.

<sup>1</sup> Vide page 319 of this number of the JOURNAL.

<sup>1</sup> Reported at the meeting of the Section for Clinical Medicine and Pathology of the Suffolk District Medical Society, March 9, 1882.

Were not the change of surroundings and the care important factors in treatment? or one might say the sanitary and moral influences were improved.

Dr. MINOT, in answer to a question, replied that the action of arsenic is not well understood, whether as a so-called tonic or in some other manner.

Dr. LYMAN inquired as to the mental calibre of the patient while at school before the attack of chorea.

Dr. MINOT replied that it was hard to judge accurately, as the child could not speak on entering the hospital, but she was very bright; more intelligent than the average of children. It is impossible to know if the child had been overworked at school.

Dr. LYMAN had a patient with chorea a year ago, who was a very ambitious scholar, and was much distressed if she was not at the head of her class. After trying various remedies without any benefit it was decided that the school was the cause of the chorea. The patient was at once sent into the country, and recovered in a short time without medical treatment. The disease lasted seventy days.

Dr. LYMAN reported a case of this kind a year ago, at which time Dr. Webber mentioned the efficacy of arsenic, but insisted that it must be exhibited in large doses. He is disposed to rely on hygiene and a change of surroundings rather than on any specific medication. He asked if fifty-six days was not a short period of duration of this disease.

Dr. MINOT thought that most cases lasted a longer time than the one reported to-night.

Dr. H. OSGOOD mentioned three cases occurring in his practice, two of which were relieved by arsenic, while the third, which occurred in a very nervous child in the country, was not benefited at all. This result was thought to be due to puberty. After five weeks, improvement commenced and has continued. This child could take only six drops of Fowler's solution. Seven drops invariably produced diarrhoea. The late Professor Traube treated chorea altogether by means of arsenic. Dr. Osgood asked if stuttering is a form of chorea.

Dr. MINOT said that he does not so consider it. Mutism is a very grave symptom and is found only in aggravated cases, the same is true of the persistence of choreic movements during sleep.

Dr. OSGOOD said he referred not to mutism but to stammering.

Dr. LYMAN inquired if there were any members present who could give the result of the arsenic treatment of chorea among dispensary patients who would not be likely to leave their general surroundings and hygiene improved as an aid to the treatment.

The Chairman asked Dr. Rotch if he could give any information on this subject.

Dr. ROTCH replied that he had treated a number of cases of chorea during his dispensary service and that they had all happened to recover in about the usual time, but that he had not given any of them arsenic, as he had considered the danger of administering the drug to this ignorant and stupid class of people to quite offset any possible good which it might accomplish. He also said that he remembered one special case where the violence of the symptoms, loss of speech, sleeplessness, inability to stand, etc., were as excessive as any which he had seen reported, and yet with iron and baths the child recovered in the usual period, the exaggerated symptoms passing off in a few days. Dr. Rotch also said that Dr. Minot's case was especially

valuable, from the careful manner in which the change in the symptoms under the use of the arsenic was noted, as this very want of care and precision makes most of the supposed results of the arsenic and other drug treatment of chorea of very little value. So far as statistics went, the treatment by drugs showed a shorter duration of the disease under arsenic than where other drugs were given, but a set of cases treated by good food and port wine averaged a recovery in from three to six weeks, which was a rather better result than that obtained by the arsenic treatment.

Dr. HAVEN had tabulated two hundred and fifty cases, but of these there were very few in which the records were thorough. Arsenic seemed to afford the best results, not equal, however, to those reported from England under expectant treatment. In one case occurring in Dr. Haven's practice seen on the fourth day, there was only a slight degree of movement on the right side. Expectant treatment was employed and the severity of the disease steadily increased. During the third week the child could neither stand, nor eat, nor speak. Efforts at speech or expression consisted only of moans. Treatment by means of arsenic was now commenced. Two days later no improvement was discernible. The arsenic was then largely increased and in two days the child showed symptoms of arsenical poisoning, accompanied by marked alleviation of the chorea. In one week there was an astonishing moderation in the severity of the symptoms. Dr. Haven had never seen so decided and sudden a change in the course of the disease. It seemed to be due to arsenic.

Dr. W. F. WHITNEY thought there might be danger in the continued use of large doses of arsenic. Dr. Wood has seen cases of fatty degeneration of the kidneys which were thought to be due to the medicinal use of this drug. Sometimes this effect occurs before swelling of the face is noticeable. In reply to Dr. C. H. Williams, Dr. Whitney said that arsenic induces fatty degeneration of all parenchymatous organs.

Dr. HAVEN asked if examination of the urine could discover the degenerative action of arsenic on the kidneys.

Dr. WILLIAMS said that his brother made some experiments on animals while in Strasburg which showed a similarity in the action of arsenic and of iron upon the animal economy.

Dr. W. A. DUNN has treated several cases of chorea with valerianate of zinc and has obtained fully as favorable results as those following the use of arsenic.

Dr. HAVEN said that it is obviously impossible to generalize cases of chorea because the causation is so different. In one severe case, accompanied by movements during sleep, the disease depended entirely upon constipation and was always relieved by a cathartic. In answer to Dr. G. B. SHATTUCK, Dr. Haven said he did not know the proportion of cases of chorea in which there were cardiac symptoms.

Dr. SHATTUCK asked if the arsenical solution was more accurately administered in drops or in some vehicle.

Dr. MINOT directs it to be given in drops. A very good way is to drop it upon bread, which is then eaten by the patient. Where carelessness in nursing is to be apprehended it is better to administer it in some vehicle containing one drop to the teaspoonful. In this way the chances of error would be diminished.

Dr. SHATTUCK asked if there would not be less

variation in the size of drops than in the size of spoons used for measuring the medicines.

Dr. MINOT thought that the variation is less in drops than in spoons. The safest way of administering arsenic is in granules.

Dr. SHATTUCK asked if patients suffering from chorea bear larger doses of arsenic than other individuals?

Dr. MINOT replied that he did not know. Children seem to bear larger doses than adults.

Dr. SHATTUCK remarked that Ziemssen prescribes from seven to twelve drops three times daily.

Dr. G. M. GARLAND said he had treated many cases of chorea by arsenic. In cases where the dose of three drops three times daily had done no good he directed five drops, rapidly increasing to twelve drops three times daily. In each case twelve drops were reached without serious symptoms, or much if any discomfort. With one exception, all the cases improved rapidly. One patient taking three drops without benefit began to improve as soon as twelve drops were given, becoming fat, strong, and healthy.

Another patient had taken arsenic, iron, etc., without benefit. Upon the administration of Fowler's solution in the dose of twelve drops three times daily, improvement immediately took place, and the case was well in a short time. A relapse occurred in this case which was also soon relieved by the same treatment.

In answer to a question, Dr. ROTCH stated that there was no form of iron specially applicable to these cases. Almost all the ferruginous preparations had been tried.

Dr. HAVEN asked the average duration of the disease in the cases spoken of by Dr. Rotch.

Dr. ROTCH could not state positively, but said it was about fifty days.

Dr. F. C. SHATTUCK then read a paper entitled

#### A CASE OF UNINTENTIONAL ASPIRATION OF THE LIVER.<sup>1</sup>

Dr. F. I. KNIGHT stated that Fraenzel almost always operated in the axillary line, and located the puncture in the fifth intercostal space on the left side, while he preferred the fourth on the right side on account of the proximity of the liver.

Dr. F. C. SHATTUCK remarked that the fourth interspace seemed unnecessarily high. In this case the free opening was made in the sixth space.

Dr. ROTCH said that Dr. Shattuck's case was especially interesting to him from its connection with the relative dangers of tapping the pericardium in different situations. It was very evident after the thorough tapping of the liver in Dr. Shattuck's case that the possibility of tapping the liver in the fifth right interspace in performing paracentesis of the pericardium would not be of much consequence, thus removing one of the alleged objections to that locality for operation, especially in comparison with the danger of tapping the heart, which was a real danger, and always existed when the pericardium was tapped to the left of the sternum.

Dr. KNIGHT said that he agreed with Dr. Rotch as to the small chance of finding an enlarged heart infringing on the fifth right interspace, but he should like to know if Dr. Rotch's further observations had led him to believe that this was invariably the rule.

Dr. ROTCH said that he had not met with or heard of a case where, during life, the enlarged heart was

found in the fifth right interspace to a greater distance than one or two centimetres from the right edge of the sternum, but that Dr. Cutler had found a case post mortem where the heart was found in the fifth right interspace, five centimetres from the sternum, and he called upon Dr. Cutler to describe the case.

Dr. CUTLER said that in this case he had found the heart in the position described by Dr. Rotch, much distended with blood, and that this distention evidently took place after death, so that it could hardly be brought up to controvert Dr. Rotch's observations regarding the possible extent of cardiac dullness, and he agreed with Dr. Rotch that it would be exceedingly rare to find the enlarged heart during life so far as five centimetres to the right of the sternum in the fifth interspace.

Dr. BOWDITCH spoke of the impunity with which most of the organs of the body may be aspirated. Often the needle penetrates structures which were not intended to be reached, but ill results seldom follow. It would be desirable to know more accurately the present condition of the patient whose case is reported to-night. The use of the term "practically well" is misleading and objectionable. We cannot feel sure within three or four months that the patient recovering from this grave disease is practically well. Dr. Bowditch asked the character of the physical signs at present.

Dr. SHATTUCK said that there was marked dullness over the lower half of the right chest, and that the respiration was very feeble, though audible to the base. Dr. Cabot reported to him that he had recently heard moist, fine rales over a spot the size of a silver dollar near the base of the lung, and in the posterior axillary line. Dr. Shattuck did not remember listening in this precise spot, and had elsewhere heard no rales. The patient has gained flesh, has had no fever for a month, and has gone to friends in the country. He has been warned that he may never regain the full use of his right lung, and may, consequently, never be able to do the hardest kinds of work. We do not know how extensive the gangrene of the lung was, and this complication may render the reestablishment of function less complete.

Dr. BOWDITCH remarked that very severe cases often recover; the chest expands to its previous volume, and after a sufficient length of time it is sometimes impossible to find any physical signs of impairment of the chest wall or lung on the side where the disease had existed. Attention was directed to the utility of manipulation of the chest wall and deep voluntary respirations as an aid to the expansion of the pleuritic side.

Dr. MINOT asked if Dr. Bowditch thought it possible that a lung which has been bound down by old pleuritic adhesions can be expanded by the voluntary efforts of the patient.

Dr. BOWDITCH replied that the expansion must be commenced early, while the adhesions are young and extensible, when it will often be found possible to expand the lung perfectly.

Dr. MINOT said that in a case like the one reported by Dr. Shattuck, there might be a thickening of the pulmonary and pleural tissues, causing the abnormal physical signs, which might gradually disappear as the patient recovered strength until nothing abnormal could be detected by examination.

Dr. A. N. BLODGETT recalled a case treated by

<sup>1</sup> Vide page 321 of this number of the JOURNAL.

Dr. Minot twelve years ago at the Massachusetts General Hospital, in which there was an enormous pleuritic effusion into the left chest. After two tapplings the fluid became purulent, when a permanent opening was made, and a drainage tube introduced and retained for some months. Dr. Blodgett has seen this patient at intervals since that time, and on examination some two years ago was totally unable to discover the physical signs of any pathological condition in the chest. Resonance and respiration were everywhere normal, and the young man performs the heaviest labors of a farmer's life without inconvenience.

Dr. KNIGHT said that cases in which a deposit of organized lymph occurs in the bottom of the chest are liable to caseous degeneration of the lung in the immediate vicinity of the lymph. The future of such cases is not promising. As long as there is a difference between the two sides in the respiratory murmur and percussion tone the patient cannot be considered safe.

Dr. T. M. ROTCH read a paper entitled

#### A CASE OF INTUSSUSCEPTION.<sup>1</sup>

Dr. W. F. WHITNEY made the following report of the autopsy, and exhibited the specimen as it was taken from the body:—

The invagination occurred at the ileo-cæcal valve, and involved about twenty centimetres of the intestine. The invaginated portion was twisted upon itself so that the lower opening was directed to one side of the axis of the gut, and pressure applied from below simply packed the sac tighter, and rendered reposition more difficult. The serous surfaces were quite firmly adherent throughout the entire extent, and the amount of force required to break them apart and replace the intestine seemed greater than one would have been justified in employing during life.

In reply to a question by Dr. Garland, Dr. Rotch stated that the child whose body was the subject of these experiments had been dead about two months, and the specimen had been preserved in alcohol.

[During the discussion of this case Dr. Whitney succeeded in reducing the invagination completely. The calibre of the intestine was fully restored, and the tissues of the bowel were not materially injured by the force exerted in reduction. The adhesions of the serous surfaces yielded comparatively easily, and the structure of the intestinal wall was found essentially in a healthy condition.]

Dr. CUTLER thought that kneading of the abdomen should be employed when hydraulic pressure is applied.

In answer to a question Dr. MINOT said that the diagnosis of invagination rested chiefly upon the circumstances of previous good health, the sudden attack, bloody discharges, the presence of a tumor, and sudden death. In such cases it might be advisable to open the abdomen, and endeavor to reduce the invagination by direct manipulation. The result could hardly be more unfortunate than if the reduction were not attempted. Dr. Minot mentioned a case he had recently seen in consultation with Dr. Fogg, of South Boston. In this case also was the same pathognomonic train of symptoms observed by Dr. Rotch, the same suddenness of attack and bloody discharges existed, but only a doubtful tumor. The diagnosis, however, was positive. After a duration of thirty-six hours a sudden alleviation of all the symptoms occurred, followed by loose

fecal dejections, accompanied by what was thought to be "bile." On the cessation of vomiting there was a small, natural defecation, after which the child commenced nursing, and soon a very large fecal defecation took place. The child is still living, but has never fully recovered from the attack. The treatment consisted of Dover's powder in small doses. In another case, occurring fifteen years ago, the only treatment employed was opiates, and the child recovered. In neither case was there any attempt to distend the bowel by water or air.

Dr. LANGMAID saw the subject of this discussion in consultation, and although Dr. Rotch was confident that it was intussusception, yet there was at that time no discernible tumor. The patient was easy under opiates. In regard to abdominal section the important question is when to perform the operation. In this case it would undoubtedly have been appropriate, but it is impossible to generalize upon its advisability in all cases. In recent reports we find the operation mentioned with increasing frequency, but we do not hear of all the cases nor of the disadvantages attending its performance.

Dr. CUTLER looked upon the fact that Dr. Whitney found so great difficulty in reducing the invagination as an indication that abdominal section would have been inappropriate treatment in this case. In California it has sometimes been the practice to introduce Seidlitz powders into the rectum and allow the disengaged gas to distend the bowel, thus exerting pressure upon the invaginated portion. Recovery followed in all reported cases.

Dr. LANGMAID thought that by abdominal section a better result would have been obtained than at this time. During life the bowel is moist and slippery and would probably be more easily reduced than after death. The fact that Dr. Whitney could successfully apply the necessary traction now would seem to indicate the same beneficial result with much less traction during the life of the patient.

Dr. WHITNEY stated that the principal difficulty at that time, as now, would probably arise from adhesions.

Dr. HAVEN asked the ratio of cures from operation in the cases spoken of by Dr. Rotch.

Dr. ROTCH stated that three of the eleven cases had recovered while eight had died.

Dr. WHITNEY asserted that in the palliative treatment of intussusception a spontaneous cure is observed in fifty per cent. of the cases.

Dr. G. B. SHATTUCK mentioned a case in Strasburg, alluded to by Dr. Langmaid, in which Koeberle removed over two yards of small intestine on account of three narrow strictures, the patient making a good recovery.

Dr. G. M. GARLAND read a paper entitled

#### ACUTE LOBULAR PLEURO-PNEUMONIA.<sup>2</sup>

Dr. BOWDITCH regarded the local symptoms in these cases as very important. These signs sometimes disappear, but often they are followed by phthisis after a longer or shorter interval.

Dr. KNIGHT asked Dr. Garland what he meant by "lobular pneumonia."

Dr. GARLAND said that he had had doubts if in the cases mentioned there was collapse of certain lobules,

<sup>1</sup> Vide page 322 of this number of the JOURNAL.

<sup>2</sup> Published on page 319 of this number of the JOURNAL.

or serous exudation into them, or if they were occupied by a fibrinous exudation.

Referring to Dr. Garland's and Dr. Knight's remarks on lobular pneumonia, DR. ROTUN spoke of the possibility of acute catarrhal or lobular pneumonia occurring in adults as in children and followed by recovery, and he reported a case seen by him with Dr. Charles Williams where the physical signs in the lungs pointed towards such a condition, though there also appeared to be a marked typhoidal element in the course of the disease.

DR. KNIGHT considered such cases extremely interesting. Three years ago he had treated such a case in Milton. The patient had had a cough for three or four weeks, followed by dyspnea, circumscribed dullness on percussion, and râles in the lower left back. These symptoms gradually extended until they occupied the whole lower lung in localized spots of augmented severity for a period of several weeks, when the disease gradually subsided, requiring between two and three months for convalescence. Since that time the patient has had no bronchitis until this year, and has presented no sequelæ. Dr. Knight had often noticed the râles described by Dr. Garland in the same locations, for a considerable time after acute disease has subsided, but had never detected dullness.

#### SPECIMENS.

DR. WHITNEY exhibited a specimen of diphtheritic endometritis, accompanied by a thrombo-phlebitis of the right ovarian vein.

The woman died thirteen days after delivery, which occurred normally at term. The thrombus had occluded completely the proximal end of the vein, while the greater part of its extent was puriform. The wall of the vein was much thickened, but there was no pus around it. The parenchymatous organs showed a marked granular degeneration.

He also showed the lungs from a case of empyema occurring in a child sixteen months old.

The right pleural cavity contained about one hundred centimetres of fetid pus. The costal pleura was gangrenous, the lung was retracted along the anterior part of the bodies of the vertebrae and covered with a greatly thickened pleura.

The apex of the lung was adherent to the chest wall and there was a free communication between the pleural cavity and a cavity corresponding to the greater part of the upper lobe, lined with a smooth pyogenic membrane, and containing a little cheesy material and pus. The lower lobe was entirely devoid of air, but normal in appearance.

A few scattered miliary tubercles were found in the other lung and the solid organs.

It was thought that the empyema was secondary to an acute trouble (pneumonia?) in the apex, which, instead of ending in resolution, had gone on to the formation of an abscess with perforation into the pleural cavity.

Adjourned at 10.30 P. M.

—The report of the Committee on Public Charitable Institutions of the Massachusetts Legislature that it is inexpedient to legislate on an order relative to discontinuing the State Board of Health, Lunacy, and Charity, and creating instead separate boards of health, lunacy, and charity, has been laid on the table.

#### PROCEEDINGS OF THE MONTHLY PHARMACEUTICAL MEETING OF THE MASSACHUSETTS COLLEGE OF PHARMACY.

B. F. DAVENPORT, M. D., REGISTRAR.

At the regular meeting of March 14, 1882, PROF. STEPHEN P. SHARPLES, S. B., gave an extensive account of

#### SUGARS, THEIR METHODS OF MANUFACTURE AND OF ASSAYING.

illustrating with specimens and polariscope.

The present government method of imposing import duties based upon the old Dutch color tests, justly applicable only to the soft Muscovado sugars, allows a modern hard centrifugal sugar, really containing as much refined sugar as No. 20 of the color test, to be entered as between Nos. 7 and 8 in color. The polariscope is the only reliable method of assay, and is that which is relied upon by sugar dealers. A very little alkali, either lime or soda, left in the evaporating pan would cover the sugar crystals with a slight coating of caramel, which gave the refiners no special trouble to remove after it has passed through the customs ranked as a sugar of a low grade on account of its dark color. The courts have decided that this is allowable so long as it is only a result of the method of manufacture of the sugar.

The pure sugar-house syrups still contain about thirty per cent. of crystallizable, as much more of the non-crystallizable, ten to fifteen per cent. of gum, etc., and four per cent. of ash. The non-crystallizable or inverted sugar consisting of equal parts of dextrose and levulose, is even sweeter to the taste than the crystallizable cane sugar. The best qualities of starch or corn sugar, as now made, is nearly equal in sweetening power to cane sugar. This corn sugar, commercially called glucose, is not exactly the same material as inverted sugar or glucose from cane sugar. The polariscope determines all admixtures above four per cent. of corn glucose with cane sugar. He found the more expensive candies in Boston were fully as likely to contain corn glucose as were the cheapest varieties, this glucose being especially adapted for the manufacture of the soft, moist candies. As a food he considered good corn glucose to be about equal in value to cane sugar. As, however, its present commercial value was only about four cents per pound, he did not consider it just to have to pay ten cents, the value of cane sugar. He did, however, consider it desirable to have it sold under its right name, and at its just value, as a healthy article of food for those who might wish to use it. At times the thick glucose syrups will change rapidly into the solid without having lost any water.

Mention was made of much of the malt extracts found in our market containing a large percentage of corn glucose.

DR. E. G. CUTLER thought this might explain his experience with certain specimens of malt extract which had been dispensed to some of his patients.

PROFESSOR MARKOE offered the suggestion that corn glucose might replace glycerine in certain pharmaceutical preparations that needed to be kept soft and moist.

MR. BARTLET mentioned gelatine suppositories as a case where it might replace glycerine.

Mention was made of the use of corn glucose for the adulteration of, or even as a complete substitution for,

honey, the deception being the more fully carried out by the substitution of an artificial paraffine for the natural bees' wax comb; further even than this, bees can be fed upon corn glucose, and they will take this material and fill up therewith an artificial paraffine comb provided for them in their hive, sealing over the cells with wax. The glucose thus used simply filters, as it were, through the bee, yet has something more of the right flavor than that which has not been thus treated.

PROFESSOR SHARLES stated that he had examined many specimens of sugars and syrups obtained in our own city and also from Michigan, and had found no such widespread adulterations therein with corn glucose as had been asserted in the Michigan State Board of Health Report as prevalent there. He believed that report to have been based upon a reliance in the coffee-reduction test for the glucose, while the reduction in very many of the cases had been really owing to other constituents present in the sugar or syrup.

### Recent Literature.

*Human Osteology.* By LUTHER HOLDEN, Ex-President of the Court of Examiners, etc., assisted by JAMES SHUTES, F. R. C. S. Sixth Edition. Philadelphia: Presley Blakiston. 1882.

It was our duty about three years since to review for the JOURNAL the fifth edition of this popular work, and, although the present remarkably handsome edition is an improvement on its predecessor, the criticisms which we made then would on the whole be still applicable. The point of our remarks was that in spite of the obvious merits of the book, the beauty of the plates, the clearness of the style, and the interest with which it clothes the dry bones, there was not the fullness and accuracy to be expected in a work of this kind. We alluded particularly to the want of description of the internal structure of the bones.

When a book has had the success of the one before us we see no reason why the distinguished author should not bring a new edition thoroughly up to the times. We may add that Mr. Holden is not entitled to any of the leniency that a beginner might claim from the critics.

Let us mention some of the omissions. Nothing is said of the double temporal ridge, a well-demonstrated point that should not have been omitted. Recent observations on the external occipital protuberance and its neighborhood are quite ignored. Not a word is said of the many and striking variations of the jugular fossa on the under side of the temporal bone, though it is a well-known fact that a description of one type of this region of the temporal bone might be quite unintelligible to the student who should follow it on a specimen of another type. There is no mention of the "true neck" of the femur nor of the interesting internal architecture of the bone. We are told, indeed, that "in the horse, the rhinoceros, and the tapir, the gluteal ridge is so largely developed that it has received the name of the third trochanter," but we are not told that it is sometimes sufficiently developed to deserve that name in the human subject, though the point is not without its practical importance. The description of the posterior surface of the patella is quite inadequate. There is no need to continue this list of omissions.

A new, and a very good, feature of the present edition is the introduction of numerous notes on comparative osteology. These, however, are not always as good as they should be. As an example let us quote from the remarks on the clavicle.

"All Primates have clavicles, to which they owe the breadth of their shoulders. In the Carnivora the clavicles do not articulate with any bone, but are simply suspended in the muscles, and are always more or less rudimentary. Bears seldom have clavicles. There is no clavicle in the elephant, or *Hyox capensis*. The three sub-orders of Ungulata have no clavicles, that is, *Pachydermata*, *Ruminantia*, *Solidungula*, as the horse and ox. The same is true of all *Cetacea*, *Sirenia*, and *Crocodylia*." Here, now, is a string of "bold, disjointed" facts that fails utterly to convey to the student the real significance of the clavicle, which is to give firm support to the shoulder in free movements of the arm, especially in such as encounter steady resistance. Thus man and apes have clavicles for climbing, grasping, pushing, etc., bats for flying, moles for digging, etc. Animals like the horse, that use their legs simply for locomotion, have no need of clavicles, and Carnivora, whose anterior extremities have a greater range of use, have in many cases rudimentary clavicles. This very simple and instructive point is utterly missed in the text.

The edition, as we have said, is a very handsome one, and, in spite of our criticisms, will no doubt be a success like its predecessors. We have no desire it should not be, for it is undoubtedly a good book, but we cannot help regretting, both for the sake of the public and the author, that, being as good as it is, it is not more nearly as good as it should be. T. D.

*Dictionnaire Annuel des Progrès des Sciences et Institutions Médicales.* Par Dr. P. Garnier. Dix-Septième année. 1881.

This volume, as its predecessors, is filled with abstracts of articles which have appeared in the medical world during the year 1881. The selection appears to have been judiciously made. The introduction gives a good *resumé* of the progress of medicine in its various departments, and the author claims that in his work all the medical events, great and small, of practical value have been mentioned.

A glance at the index shows that the author keeps himself well informed regarding the work of American physicians. Reference is made to articles published by Drs. Bigelow, Bixby, Van Buren, Curtis, Da Costa, Delafield, Emmet, Gross, Hammond, J. Homans, Thomas, J. C. Warren, and others.

We take pleasure, as in previous years, in recommending this work to the profession. \*

*Aids to Rational Therapeutics.* By J. MILNER FOTHERGILL, M. D., M. R. C. P. New York: G. P. Putnam's Sons. 1882. 121 pages.

The author suggests briefly a line of treatment for various symptoms, and gives some useful hints, but the reader must not have too much faith in all that is said, else he will be disappointed.

Numerous prescriptions are given, many of which are good but not new.

The material is not well arranged, and there is no index.

## Medical and Surgical Journal.

THURSDAY, APRIL 6, 1882.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

## THE TREATMENT OF THE CRIMINAL INSANE.

The question of providing for the criminal insane has been brought to the attention of the legislature of Massachusetts again this year, and this time upon a petition from the trustees of all the State insane asylums, by the strong recommendation of the Prison Commission, and with the decided approval of the State Board of Health, Lunacy, and Charity. It can hardly be supposed that so urgent a demand for a matter of such evident need will be refused. In considering, therefore, our own requirements in this direction, it is desirable to ascertain what has been done elsewhere, and to learn how far we can benefit by others' experience.

The criminal lunatic asylum in Broadmoor, England, was opened in 1863. During the previous eight years the number of criminal lunatics under detention in England and Wales in asylums increased annually from 686 to 1017, and there were thirty-eight escapes of convicts who were not captured before the end of the year. In the succeeding seventeen years the corresponding facts are shown in the following table:—

| YEAR.   | IN LUNATIC HOSPITALS.              |  | IN BROADMOOR ASYLUM.                            |  | Total Number in Asylums and at Broadmoor. |
|---------|------------------------------------|--|---|--|---|
|         | Criminal Lunatics during the Year. | Escaped and not captured by the end of the Year. | Criminal Lunatics in Broadmoor during the Year. | Escaped and not captured by the end of the Year. |   |

Fifteen times as many insane convicts per one thousand escaped from the lunatic hospitals as from the criminal asylum. Of the five from Broadmoor three were never recaptured. During the first six years there was a gradual removal of the insane from the insane asylums, but in the last twelve years the numbers remaining in them have been tolerably uniform, from 250 to 348. In the sixth year after the

opening of the criminal asylum the greatest number of convicts were confined in it, there having been a progressive annual increase, while the latter eleven years show a quite regular filling of the building to its full capacity without overcrowding. It may be seen, too, that the total number of the criminal insane kept in confinement outside of the prisons is very much less in the last eleven years than in the first six. In other words, experience has shown that in England, at least, the ends of justice and humanity are thought to be best served by retaining in the prisons a larger number of the insane than was formerly the custom, and by keeping in the insane asylums a great part of the criminal insane who are not dangerous. The whole of the insane female convicts under sentence of penal servitude are removed from prison to Broadmoor immediately upon their insanity being recognized, but the male convicts are not at present ordinarily transferred until the periods of penal servitude to which they have been sentenced have nearly expired, and special provision for their treatment has been made in the convict prison at Woking.

From the opening of the Broadmoor Criminal Asylum to the end of 1880 there were 59 persons returned to different prisons on recovery, and 108 were discharged out of custody, of whom five were sent back, and six were readmitted at their own request, *recognizing their insanity, and fearing their inability to restrain themselves from crime.*

Of the 370 men and 120 women in the asylum at the close of 1880, 77 were certified to be insane while under sentence, 244 had been acquitted on the ground of insanity, 13 were reprieved on that ground, 117 were found insane on arraignment, and 39 were certified to be insane while awaiting trial or judgment. There were 220 whose crime was murder, 10 manslaughter, 122 attempt to murder, maim, etc.; concealment of birth 2, rape 3, common assault 7, assault with intent to ravish 6, unnatural offense 3, treasonable and seditious offenses 3, burglary and house-breaking 16, robbery with violence 1, sheep-stealing 2, horse-stealing 1, larceny and petty thefts 25, arson and malicious burning 28, willful damage 2, forgery 1, uttering counterfeit coin, etc., 1, deserters from army and navy 2, felony 4, other misdemeanors 3, sending threatening letters 3, insubordination as soldiers 18, attempting self-murder 3, libel 1. Of the 81 murders by women, 68 were of their own children; of 148 by men only 25 were of their own children. Eighteen persons had been killed by fellow-patients in asylums.

Of the 1349 admitted from 1863 to 1880, inclusive, 108 "recovered" and were discharged; 59 "recovered" and were removed to prisons; 452 became harmless or demented and were transferred to insane asylums; 234 died.

Of 62 admitted in 1880, the leading three supposed "causes" of the insanity were hereditary in 8, congenital in 6, including two cases where there were also intemperance or injury to the head, intemperance in 5.

In forty post-mortem examinations during the year 1880 there was only one case where the condition of

the brain or its membranes did not indicate marked disease. Only one who has seen the wonderful skill in the management of the asylum by its medical superintendent, Dr. Orange, and who knows the liberality with which the government provides for it, can appreciate the facts that the labor performed by the criminal insane in the asylum in 1880 had a money value of £2,835; that there were no serious accidents, suicides, or escapes, and that no form of what is known as mechanical restraint was used during the year.

During 1879, the latest year for which these statistics are available, there were for England and Wales, with a population fifteen times as great as that of Massachusetts, 323 criminals in insane asylums, 528 in the Broadmoor Criminal Asylum, and in prisons 294 cases of insanity, of whom 21 men and eight women were removed to insane asylums or to Broadmoor. The teachings of English experience are that:—

(1.) The expense of caring for the criminal insane must be at least double that for the other insane, although a great deal of work can be expected of both classes.

(2.) Male convicts becoming insane while serving sentence are kept in prison, as a rule, until their term of punishment is nearly over, partly because Broadmoor is so full that new buildings would need to be put up for them if they were sent there, and partly because it is thought desirable to keep them where the life is most like punishment, and to prevent as far as possible attempts at simulation.

(3.) The criminal insane are transferred from the criminal asylum to the lunatic hospitals as soon as their condition justifies the change.

(4.) In round numbers, in 1879, twenty of the criminal insane per million of the population were confined in the criminal asylum, twelve in lunatic hospitals, in prisons ten (on the supposition that the 294 cases of insanity represent about 260 persons).

(5.) The number of the criminal insane really cured or curable is so small (not over six per cent., counting relapses and recurrent attacks) that the protection of society is the chief thing demanded in their treatment.

(6.) Provision for their confinement is of three kinds: in the prisons, chiefly in special cells or rooms; in an asylum as secure in all respects as a prison but entirely remote from one, and in the ordinary insane asylums.

#### MEDICAL INSPECTION OF THE PUBLIC SCHOOLS OF BOSTON.

FOR some years an earnest effort has been made to appoint a medical inspector or supervisor for the public schools of this city, but so far, strangely, without result. That such an office is a public necessity may be inferred from the following statistics. For the twenty-five years immediately preceding 1877, it is estimated that 5000 deaths from scarlet fever, a disease almost entirely confined to childhood, occurred in Boston from the unrestrained dissemination of its

contagium.<sup>1</sup> During the years 1874, 1875, and 1876, there were 1282 deaths from the same cause, and in 1875, 418 from diphtheria.<sup>2</sup> In the State of Massachusetts, during the year 1880, 2081 persons died from various causes between the ages of five and fifteen, or during school years.<sup>3</sup> These are the actual deaths, the statistics not taking into the account the serious and lasting impairment of health so often produced by these contagious diseases, particularly scarlet fever. There are two other diseases to be guarded against, namely, whooping-cough and measles, which, ordinarily considered harmless, are yet capable of leaving the constitution enfeebled for some time, pneumonia, bronchial difficulties, and even pulmonary consumption not infrequently supervening.

There is no good reason why all these contagious diseases may not be spread by the public schools. On the contrary, there is every opportunity for such a result with children, either actually suffering from disease or coming from an infected house, crowded together in, as it too often happens, a badly ventilated room, and coming into contact with each other. This fact has been clearly proven by the testimony of many distinguished physicians at the various hearings which have been held upon this subject. Dr. C. F. Folsom stated at the session of the Committee on Rules and Regulations of the Boston School Board, held November 23, 1876, that "a single child, sent to school before entire recovery from scarlet fever, in one of the *arrondissements* of Paris, in 1875, has been clearly shown to have been the direct cause of a hundred and fifty cases, of whom eighteen died." Moreover, either through ignorance or carelessness, excusable or not, on the part of physicians and parents, it has frequently happened that children suffering from a very mild attack of a contagious disease have been allowed to attend school, thereby serving as *foci* from which the graver forms of the disease have spread. By an intelligent and systematic understanding between the teachers and the medical inspector such occurrences could, as a rule, be avoided.

To be sure there are rules of the Board of Health which regulate the attendance on school, within certain limits of time, of any child who is suffering from a dangerous contagious disease, or who comes from a house wherein such a disease exists. But who is to watch that these rules are not disobeyed—for that they are disobeyed there can be no question? The machinery for the enforcement of these regulations is excellent, but, unfortunately, it is in many cases practically useless, by the admission of those members of the School Committee most competent to judge, from want of the proper official to keep it constantly and understandingly in motion.

Nor are the contagious diseases the only evils which arise from inadequate sanitary supervision of the schools. To quote from an editorial in the *JOURNAL* of October 26, 1882: "During the past year 2213 persons have died (in Massachusetts) between the ages of fifteen and thirty, from pulmonary consumption, out of

<sup>1</sup> Boston Medical and Surgical Journal, March 23, 1876.

<sup>2</sup> Boston Medical and Surgical Journal, January 18, 1877.

<sup>3</sup> Boston Medical and Surgical Journal, October 26, 1881.

a total of 5494 for all ages, a disease the chief causes of which are innutrition and re-breathing over and over again air which has been vitiated, or, in other words, taking into the lungs what has been very properly called the sewage of the atmosphere." That this vitiation of the air, due to improper ventilation, over-heating, and sewer gas, is always present in some of our school-houses, the impairment of health in those who spend so much of their time in it sufficiently attests. The important subjects of ventilation and heating, therefore, demand the most vigorous and constant supervision.

Another very important part of the duties of a medical inspector should be the delivery of a course of lectures on practical hygiene to the teachers and to the advanced classes of the higher schools. The diffusion of useful knowledge claims, at the present day, the attention of all who have the good of communities at heart. What better method could be devised for disseminating a knowledge of the laws of health than by such a course of lectures to instructors and to those who annually graduate from our schools to become useful citizens? The great difficulty with which physicians and boards of health have to contend in the prevention of disease is the lack of intelligent co-operation on the part of those who are most directly affected by unsanitary surroundings. If this loaf of ignorance could be leavened by the diffusion of useful hygienic knowledge, we venture to say that sooner or later there would be a higher standard of health in the community, far reaching in its effects.

It can be readily understood, therefore, that the scope of this office is almost unlimited. That the Board of Supervisors, with its multitudinous duties, can thoroughly attend to the many sanitary details which affect the health of school-children, such as heating and ventilation, light in relation to the scholars' eyes, seats and the deformities traceable to them, gymnastics, condition of the nervous system, contagious diseases in the schools, etc., is not possible. Not even with plenty of time at their disposal, nor with the best of intentions and earnest desires to improve hygienic shortcomings, which they undoubtedly possess, are the members of this Board, as now constituted, fitted by previous training to take cognizance of ills which any sanitary expert would be able to detect. Consequently they are unable to properly guard the health of the children under their care. It has been said that the Board of Health is the proper authority to investigate and report upon the sanitary condition of the schools, and the proper hygienic management of the scholars. This Board, however, emphatically proclaims that it cannot attend to these duties properly; that should it undertake to perform this additional work it would be obliged to appoint just such an officer as ought to be appointed by the School Committee. It has been admitted that many sanitary recommendations have been made by this Committee through the Board of Health, which have accomplished nothing. This, we believe, is simply because there has been no special agent to follow these reports to the fountain head, to argue, and to dis-

tinctly and clearly prove the necessity for their provisions being carried out.

If the Supervisors, School Committee, or the Board of Health, either separately, or together, are able to attend to this important work of sanitary inspection, why, it may be asked, do we continue to see such startling statistics as those given at the commencement of this article; why do we continue to see such instances of impaired constitutions as annually graduate from our schools; why is the best medical and sanitary talent of the country so earnestly arrayed in favor of special sanitary supervision of school-houses and scholars? A few years ago many of the leading physicians of Boston signed an earnest request that the office in question should be created. The late Dr. E. H. Clarke wrote on March 19, 1877, as follows: "I write chiefly to say that my professional experience has long since convinced me that the sanitary supervision and inspection of the children, school-houses, and surroundings of our public schools by a competent inspector would do a great deal towards improving the health, strengthening the physique, and diminishing the diseases of our school-children. Teachers and pupils would both be benefited, and the result would be one of incalculable advantage to the community." The scheme has also received the indorsement of the present Superintendent of Schools, as well as that of his two predecessors. Mr. Philbrick said at a hearing held on November 23, 1876: "If we would work the brain to the best advantage we must see that the requisite physical conditions are secured." "It is not at all probable, judging by the experience of the past, that we shall produce the results that are to be desired, except through the labors of a competent person especially employed for this specific purpose." "Here are fifty thousand children in school, every one of whom would probably be benefited directly."

It cannot be that these gentlemen are entirely wrong; that their years of experience have led them to entirely erroneous conclusions from the facts so commonly noticed by them. The advocates of this reform make the distinct issue that a medical officer, if he is competent and not hampered, can, by constant inspection, prevent much of the impairment of health which exists under the present system, and that he can, with efficient co-operation, prevent in a great measure the spread of the various contagious diseases, peculiar to childhood, through the agency of the schools. Let, therefore, the plan be tried; let the proper officer take charge of all matters pertaining to the health of the city's wards, as far as relates to their connection with the schools, and we are convinced that with the proviso mentioned above, there will be results commensurate with the importance of the subject. This has certainly been the case in Brussels, where medical inspection of the schools has been carried on since 1874, as may be learned from the following extract from our editorial previously quoted: "as a result, *no one of the infectious diseases has reached the height of an epidemic in Brussels since the establishment of their inspection of schools, although other cities of Belgium and Europe have suffered severely; the*

general health of the pupils has improved, and the scholars have much more nearly than before that training which is suited to them individually." These conclusions come home very forcibly to those in our community who have lost children (and their numbers are not few) by diseases directly traceable to the public schools. They, as well as all other parents, have a right to demand that this trial should be made, and that in the future the health and lives of their little ones should be protected by all means known to modern science.

An exceptional opportunity is now presented for the appointment of a medical officer, since five very efficient members of the Board of Supervisors have been chosen. By all means let the sixth member be a physician skilled in sanitary science, who, as a supervisor, will not cause any additional expense to the city, an objection which has been raised against the creation of a special office. That there can be no valid objection to this officer being a member of the Board, even though with his particular duties he may be unable to attend to all the duties of general supervision, is evidenced by the fact that at the last meeting of the School Committee a very respectable number were of the opinion, as expressed by their votes, that the whole work could be done with even less than five supervisors. Boston, which so invariably takes the lead in all matters of reform, has now a grand opportunity to increase her good name, and her School Committee, which is recognized as a very able body, has the same chance of adding to its reputation throughout the country by leading the van in this important matter.

Boston schools are looked upon everywhere with admiration; let this admiration be deepened by allowing them the medical supervision which must sooner or later come. If Boston falters now, other cities will out-strip her in this race for improvement. Is it not better, therefore, to heed the handwriting on the wall of enlightened public opinion, and by a timely acceptance of the warning, lead rather than follow?

#### MEDICAL NOTES.

—The total number of new cases of small-pox originating in Boston during the month of March was six. One new case was reported on April 3d, supposed to have originated from handling rags.

—Thomas Potts James, the eminent bryologist, died recently at Cambridge, at the age of seventy-nine. Until within a few hours of his death, Mr. James was working on a Manual of North American Mosses, which he, in connection with M. Leo Lesqueux, was preparing for the press, giving the result of the study of the past forty years.

#### NEW YORK.

—The fifty-second annual commencement of the College of Pharmacy was held at Chickering Hall on the 22d of March, when diplomas were conferred upon eighty-six graduates. A portrait of Professor Chandler was presented to the College by the graduating class on this occasion.

#### Miscellany.

##### FORTRESS MONROE AND OLD POINT COMFORT AS A WINTER RESORT FOR INVALIDS.

MR. EDITOR.—Some of your readers may be interested in a few particulars about Old Point Comfort, where I spent several days very recently, and which has, especially within a year or two, attracted such large numbers of Northern people during the winter and spring months. The more physicians know about places to which they send their patients, the better for both parties, and the more rare those case of woeful disappointment which are more common than they should be.

In the first place, as to the journey. This is rather long, but cannot be said to be very fatiguing. The easiest way for most people is to go to New York, either by boat or rail, and take the train with drawing-room car, leaving Jersey City at 3.50 P. M. This train makes close connection with the Bay Line steamer for Norfolk about nine P. M., near Baltimore, the passenger stepping almost directly from the car upon the boat. Another way is to leave Boston by the New York and New England train at six P. M., and go through to Baltimore without change of cars, arriving at nine A. M. One must then pass the whole day at Baltimore, and drive across the city to take the boat at seven P. M. The boat then drops several miles down the stream to another dock, to await the New York train. The steamers of the Bay Line are very comfortable, provide excellent food, and have, besides state-rooms, a number of larger rooms with beds. The passage to Old Point takes about twelve hours, and one is landed at the very door of the hotel. A boat leaves Washington also every evening except Sundays, but this line is said to be decidedly less comfortable than that from Baltimore. Those who are unwilling to take any risk of seasickness can reach Old Point by rail through Washington and Richmond. The passage from Norfolk is only ten or twelve miles.

The hotel—there is but one, the Hygeia—is an enormous wooden building immediately on the beach, and within almost a stone's throw of Fortress Monroe. It is provided with broad piazzas on almost every story, and many of these are glassed in during the winter months. It is heated by steam, and, in the newer portions, nearly every room has an open grate adapted for either soft or hard coal. In the older parts of the hotel there are steam radiators in every room, and but few have open fireplaces. Baths of hot and cold sea and fresh water can be had in the hotel, and a few rooms are provided with private bath-rooms. There are elevators. The corridors of the hotel are draughty, an objection for those who take cold easily. Rain water is used for drinking purposes, and the drainage of the hotel seemed to be good, but I did not have time to investigate this point thoroughly. There was a bad smell near one set of water-closets while I was at the house, but this was due to the clogging of the soil pipe by a pistol which fell from the pocket of one of the guests while using the closet. This is a danger connected with the carrying of deadly weapons which has not been alluded to before, to my knowledge. The cooking and service were very fair, better than I should have expected at such a place. The hotel was not at the time of my visit full, and I should think it doubtful whether the kitchen and dining-room accom-

modations are at present sufficient for a full complement of guests, seven hundred to one thousand. Oysters are very abundant and good, and are provided in almost every style at every meal. I can testify that broiled oysters for breakfast are neither unpalatable nor unwholesome.

Full precautions are said to be taken against fire, a danger which naturally occurs to one occupying a room on the fourth story of a large and rather rambling wooden building rendered dry as tinder by steam heat.

As to the climate I do not propose to say much. It is of course far milder than with us, and there are undoubtedly many days throughout the winter when one can sit in the fresh air, well wrapped up. In the latter part of February I saw violets in bloom in the open air. Anybody can see for himself, in his daily paper, the relative temperature of Norfolk and Boston in the weather report.

The hotel is very full during March and April, and it is not easy to secure good rooms at this time. One may write to a friend to secure rooms, and they may be promised by the proprietor, but they are not secure until one is established in them. For a person who is well and strong this may be no great hardship, but an invalid or delicate person would find a great difference between the south and north rooms. During the winter months, *stricto nomine*, the house is amply large for all present demands, and I do not think that this difficulty of securing rooms would be encountered. It is not wholly the fault of the management. People often say that they are going away on a certain day, their rooms are then promised to others, and later the first party concludes to stay for another week.

During the spring months, at least, many of the guests are people in good health, who merely wish to escape a few of our east winds, and the place is consequently less depressing than those resorts to which only invalids go.

Hotel life is, at its best, undesirable enough for young children, but at Old Point there is one very great advantage in the fine, clean beach, which immediately adjoins the piazzas. At the time of my visit babies were on the piazzas in their carriages, and older children on the beach playing in the sand, making forts, etc., nearly all day long. There is rarely or never any surf of consequence; the rise and fall of the tide is small, — I should judge not more than two or three feet, — and there are many shells to be picked up of kinds with which we are not familiar along our coasts. At low tide one can drive over the beach, which is said to extend for fifteen miles toward the Chesapeake.

The resources of the place in the way of occupation and amusement are not very varied, but are still sufficient for those who are not very exacting. A good shell road goes to Hampton, where are the Soldiers' Home — exclusively for disabled volunteers of the civil war — and the Normal School, with its Indian and negro pupils. Sail boats are to be had, but row boats are very hard to find. There is a daily dress parade in the fort, which is open all day in the freest possible manner, and there is a military band. Within the fort are groves of live-oaks, and, about the officers' quarters, specimens of box, holly, and evergreens which would enrapture a Northern gardener. Large numbers of steamers and sailing vessels are constantly passing to and fro from Hampton Roads and the James River, and one or more ships of war are generally lying within sight of the hotel.

A lady who has passed the larger part of every winter for many years at Southern or West Indian health resorts said to me: "This place is rather too cold for me, but offers far greater advantages for my children than places such as Aiken, Thomasville, etc.; and, moreover, if I do not feel up to driving or walking, the constantly changing sea and passing vessels give me something to look at from the piazza or my room."

Last, but not least, Dr. Hoff, the surgeon at the fort, is a skillful and kind physician within easy call.

In short, the impressions which I formed of the place during my short visit were very favorable, and it seems to me to have great advantages for delicate people without serious organic disease, or for convalescents from acute diseases who require plenty of pure fresh air, rest, and change of scene, combined with a very fair degree of comfort, in order to regain strength rapidly and pleasantly. Very truly yours,

FREDERICK C. SHATTUCK.

Boston, March 25, 1882.

#### LETTER FROM PHILADELPHIA.

MR. EDITOR. — Matters of interest have recently occurred that deserve more than a passing notice. The death of Professor Joseph Pancoast has been quickly followed by the resignation of Professor Gross from the Chair of Institutes and Practice of Surgery in the Jefferson Medical College; this action being taken on the 29th of March, the day before the College Commencement. The reasons assigned by the venerable professor in his letter to the Trustees are as follows: —

"Advancing age and a desire, after a laborious professional life of fifty-four years, to spend the remainder of my days in comparative repose, induce me to ask your Board to accept my resignation of the Chair of Surgery which, by a unanimous vote, they did me the honor to confer upon me twenty-six years ago. During this long period it was my good fortune to be associated with learned, distinguished, and honorable colleagues, who always received my earnest coöperation and support in every measure designed to advance the best interests of the school, and to maintain it in that lofty position which it is universally acknowledged, both at home and abroad, to occupy.

"In severing my relations with you and with my associates, I desire to assure you that I shall ever feel a deep interest in my Alma Mater, and pray that she may continually advance in prosperity and influence, and be in all time to come an honor to her founders, to the various faculties that have ministered to her shrine, and to the Trustees who have, in successive stages of her career, so wisely shaped and controlled her destinies. I lay down the robes of office not without regret, but with clean hands and with the consciousness that in all my teachings, extending in different schools over a period of forty-eight years, I was ever governed by an eye single to the welfare of my pupils, and the honor and dignity of my profession."

The Board of Trustees, after accepting the resignation, unanimously elected him Emeritus Professor of Surgery. It was decided to divide the Chair and to give to Dr. S. W. Gross the Professorship of Principles of Surgery, and to Dr. John H. Brinton Practical Surgery, the duties of the Surgical Chair being also divided. This apparently relieves the Professor of Anatomy of his clinical labors. Professor Gross, Senior, will, as his health permits, attend the clinic with his son, and continue the valued instruction that has given Jefferson its great reputation as a school of surgery, in which its preëminence has long been recognized.

The annual oration before the Alumni Association of Jefferson College was delivered March 29th, in the hospital amphitheatre, by Professor L. Elberg, of New

York, whose theme was Modern Progress in Biological Science. It was an excellent *résumé* of the achievements in the special field of research indicated in its title, and formed an interesting and very scholarly address. After the lecture a supper, at which fifty-two sat down, was given in honor of the orator, at the Hotel Bellevue, by the resident Alumni, Professor Gross, Sr., President of the Association, occupying the head of the table. It was the most successful gathering of the Alumni that has yet been held. The endowment of Jefferson College was discussed, and a movement instituted in this direction by appointing a committee to consider the subject, receive subscriptions, and report at the next meeting.

The eighty-third Annual Commencement of Jefferson was held on March 30th, at which the degree of Doctor of Medicine was conferred upon two hundred and forty-seven graduates. The honorary degree of Doctor of Divinity was conferred upon Rev. Isaac L. Nicholson, of St. Mark's P. E. Church, Philadelphia, and Rev. Charles A. Maisson, of St. James Church, Kingessing. The honorary degree of Doctor of Laws was conferred upon Dr. Thomas Adlis Emmet, of New York. Professor H. Chapman delivered the valedictory address.

The University of Pennsylvania held its one hundred and fifteenth Annual Commencement on the 15th ult., at which one hundred and sixty-three students were graduated, (one hundred and twenty-two in medicine, forty-one in dentistry); Professor Jas. Tyson delivered the valedictory address. University propriety and traditions were studiously observed by the wearing of the caps and gowns by the faculty and class with a decided effect; in one direction a new departure was made, however, that deserves to be imitated even by those who are not equid to the other; the graduating class requested that no flowers should be sent, and as a result the flower nuisance was happily distinguished by its absence.

The Women's Medical College held its Commencement on March 16th, the degree being conferred upon nineteen women. Professor J. B. Walker delivered the valedictory. The Medico Chirurgical College held its first Annual Commencement in Association Hall, the valedictory being delivered by Professor Wm. F. Waugh, to three graduates.

The sixty-first Annual Commencement of the Philadelphia College of Pharmacy was held March 15th, at the Academy of Music. One hundred and seventeen graduates received the degree of Graduate in Pharmacy. Professor Samuel P. Sattler delivered the valedictory.

Philadelphia as a medical centre was never more flourishing, its time-honored schools are steadily increasing in usefulness and influence, and they have by a marked degree conformed to the popular demand for higher medical education by extending the curriculum and the period of study; the classes are large, hospital facilities for students are numerous, and if further evidence were needed of its position in medical teaching it may be found in the fact that it publishes seven medical journals, devoted to general medicine, without counting those of dentistry, pharmacy, and other specialties, or annual volumes of transactions.

The medical societies are quite numerous and show increasing activity. The College of Physicians had measures on foot to establish a Nurse Registration under the charge of a committee consisting of Dr. W. W. Keen, chairman, and Drs. S. Weir Mitchell and Al-

bert H. Smith, which has commenced work with great energy, and has secured subscriptions of over twelve hundred dollars in order to pay the necessary expense for the first year. The books will probably be opened by May 1st for the registration of nurses. The College is also to have its library opened in the evenings, to have a smoking and conversation room, a telephone, and a number of other modern conveniences. The library is rapidly increasing at the rate of one hundred or more volumes per month, and new cases are being put up to accommodate the rapid accumulation. The books are in excellent order, the card catalogue is approaching completion, and increased conveniences have been adopted to facilitate consultation of books, the librarian having the services of two assistants. The meetings of the college also show increased interest, and are more largely attended than they have been for a number of years.

At the last meeting of the County Medical Society, Dr. Frank Woodbury read a paper upon a Rational Treatment of Pulmonary Consumption, in which he spoke of chronic tuberculosis as a disease of nutrition, specific only in the sense that it has a recognizable morbid anatomy and clinical course, but not specific in its causation. The rational treatment that he considered appropriate being: (1) to relieve urgent symptoms, (2) to improve the hygienic conditions of the patient, and (3) to remove the dyscrasia by systematic exercise, living in elevated regions, and breathing pure, dry air. He condemned the alcohol treatment and the abuse of opium, advocated the use of the ordinary alteratives and anapleptics, but considered an out-door life as of primary importance.

The Mutual Aid Association held its Annual Meeting on April 3d, Dr. William Pepper, president of the Association, presiding. The usual business was transacted. Dr. R. J. Dunglison reported a balance of nearly \$3000 in the treasury. By the rule of the society no money can be disbursed for charity until the funds amount to \$5000. Several cases of distress were reported, which were partly relieved by private subscription among the members. The Association has an important work to perform, and will undoubtedly accomplish a great deal of good. Only members of the County Medical Society are eligible for membership.

#### IN RE GUITEAU.

MR. EDITOR, — It seems hardly necessary for me to repeat for the third time my statement that there were two measurements taken of Guiteau's head, one at the longest circumference by lead pipe, and one higher up, at the plane of the parietal. Dr. Kempster testified (see page 1522 of the evidence) that his "shape" was taken with a *conformateur*. This "shape" was that taken by Steinmetz, the Washington hatter, and shown to the principal medical witness for the defense (page 1005) as well as to one or more of the government witnesses.

As you well know, the cuts in my previous letter were reduced by the publishers of the JOURNAL by photographic process from the plates in the government report, so they are presumably accurate.

No reliance can, I think, be placed upon Clark Mills' mould of Guiteau's head. There are at least three casts from this in New York, each one of which differs from the other. In the evidence it is admitted that

the "face part of the cast had been smoothed out because Guitau smiled." It is the opinion of many, who should know, that the sculptor's peculiar phrenological views have led him to use his trowel in a ju-

dicious way upon other parts of the head. This would appear, after inspection of two of the casts now in this city, to be highly probable.

ALLAN McLANE HAMILTON.

# REPORTED MORTALITY FOR THE WEEK ENDING MARCH 25, 1882.

| Cities.                         | Population by Census of 1880. | Reported Deaths in each. | Deaths under Five Years. | Percentage of Deaths from         |                |                       |                |            |

**APPOINTMENT.**—**KALLOCH, PARKER C., M. D., of Pennsylvania,** having passed successfully the examination required by the Regulations, was appointed an assistant surgeon, by the Secretary of the Treasury, January 23, 1882.

**THE SECTION FOR CLINICAL MEDICINE AND PATHOLOGY OF THE SUFFOLK DISTRICT MEDICAL SOCIETY** will meet at 19 Boylston Place, on Saturday, April 8th, at 7.45 o'clock. Papers: Dr. Hall Curtis, A Case of Addison's Disease, with Autopsy. Dr. E. W. Cushing, Pseudo-Membranous Laryngitis complicating Typhoid Fever and causing Death. Dr. W. A. Dunn, and Dr. H. I. Bowditch, The Therapeutics of Venesection. Dr. S. W. Langmaid, A Case of Intussusception, with Recovery. F. S. Billings, S. V., Experiments on the Stomach and Intestine in Animals.

It is important that the meeting should open punctually at the time appointed. **ALBERT N. BLONGETT, Secretary.**

**MASSACHUSETTS COLLEGE OF PHARMACY.**—The regular monthly pharmaceutical meeting of the College will be held at 7.30 p. m., on Tuesday, April 11, 1882, in the College Hall, No. 1151 Washington Street. Mr. Henry W. Lincoln, Pharmacy Laws, are they Desirable? Discussion pro and con. All persons interested in pharmacy and collateral pursuits are invited to be present. **DR. B. F. DAVENPORT, Registrar.**

**THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT** will meet April 10th, at 8 p. m., in the Medical Library. Dr. Porter will report some cases of Popliteal Aneurism, and there will be a discussion on the Surgical Treatment of Aneurism. Election of new members.

SUBINVOLUTION OF THE UTERUS.<sup>1</sup>

BY A. D. SINCLAIR, M. D.

ABOUT ten years ago I made a communication to this Society, on subinvolution of the uterus, in which was given the details of several cases, chiefly under my care at the City Hospital. At that time this disorder was seldom, if at all, recognized by the general practitioner, who, though not ignoring the possibility of its existence, was skeptical as to its reality. But the times have changed. We live and learn. Much has been written on this subject, of late, at home and abroad, and all the best recent systematic treatises on diseases of women have each a chapter devoted to its consideration. The disorder to which Simpson, in 1852, gave the name of subinvolution of the uterus existed at all times, as now, but the affection was regarded as one of chronic inflammation of the uterus, and as such described and treated. It was the work of the facile principles of modern gynecology that first led to its true appreciation in an article entitled *Morbid Deficiency and Morbid Excess in the Involution of the Uterus after Delivery*.

What is the recent idea as to the pathology of subinvolution of the uterus? Dr. Thomas, in accordance with the results of his own researches, and the views of other writers and observers, has adopted the term "areolar hyperplasia" as being the condition present in this disorder. He says,<sup>2</sup> "The vast majority of cases are due to interference with that retrograde metamorphosis occurring in the puerperal uterus styled involution."

The normal uterine elements, according to Arthur Farre in the *Cyclopedia of Anatomy and Physiology*, are five in number, namely: (1.) Fusiform fibre cells or smooth muscular fibres. (2.) Round or oval nuclei, or elementary corpuscles. They are apparently an embryonic condition of the fusiform fibre cells. (3.) Amorphous or homogeneous connective tissue in an unformed state constituting a transparent matrix in which the fibre cells and nuclei are imbedded. (4.) Fibrillated connective tissue, white fibrous tissue found chiefly among the middle and outer muscular laminae, serving here the purpose of a connecting medium between the several layers, and supporting the blood-vessels ramifying between them. (5.) Elastic fibrous tissue. These several tissues, together with the blood-vessels, nerves, and lymphatics, constitute the structure of the uterus, which is covered with serous membrane or peritoneum, and lined with mucous membrane. There is this difference between the body and the neck of the uterus, that while in the former the muscular element predominates in the latter the fibrous prevails.

Impregnation causes a wonderful change in the uterine tissues, vessels, and nerves, which grow and develop rapidly. Kölliker states that, in addition to the development and growth of preëxisting tissues and cells, "a new formation of muscular fibre also takes place." Simpson, in this connection, writes as follows: "During the forty weeks of utero-gestation the uterus enlarges from nearly three inches in length and one and three quarters inches in breadth, to twelve

or fifteen inches in length and nine or ten inches in breadth. It increases from two ounces in weight to twenty-five or thirty ounces. The cavity of the uterus before impregnation is less than one cubic inch, while at the full term of pregnancy it is extended to above 400 cubic inches; and the surface of the organ increases from about five or six square inches to nearly 350 square inches. Before impregnation the uterine cavity would not hold above a drachm or two of fluid; at the ninth month of utero-gestation its contents usually weigh from 120 to 150 ounces. The rapidity, however, with which the uterus diminishes in size after delivery is perhaps still more marvelous than the rapidity with which it increases in size after impregnation. The celerity of its involution in the puerperal state is a fact more striking and remarkable than the celerity of its evolution during the pregnant state; . . . whilst the human uterus takes forty weeks to attain the dimensions pertaining to the fully developed state of pregnancy it requires only, on the contrary, from four to eight weeks to decrease from the extreme size peculiar to pregnancy down to the small size peculiar to the same organ in its unimpregnated condition."

But in the vital mechanism of the involution or reduction of the uterus after delivery, various pathological derangements are liable from time to time to occur. This, like every other process in the animal economy, is apt, for example, to fail, either in the way of defect or excess, involution becomes impeded or arrested, and the organ is in consequence liable to be found weeks or even months—he might have said years—after parturition, still so large and unrelaxed as at first to be readily mistaken for a tumor of the uterus or ovary." Simpson then relates the following typical case of arrested involution, and, so far as I know, the first on record. "During the summer of 1842," he writes, "I attended, along with Dr. Abercrombie, a lady who, after a premature confinement in the country, had suffered from a smart attack of puerperal fever. After so far recovering for a few weeks, she was sent from a considerable distance into town, to be treated for what appeared to be a large tumor, stretching upwards from the pelvis into the right iliac region. The tumor had not been observed before delivery, and was somewhat painful to the touch. It seemed at first sight extremely doubtful whether the mass consisted of an inflamed uterine fibrous tumor, or enlarged ovary, or of one of those chronic purulent collections which are apt to form towards one or other iliac region in connection with puerperal fever or inflammation. The uterine sound, when introduced into the os uteri, passed easily and directly upwards for several inches to the superior end of the tumor, and its apex could be felt there by the hand placed externally. This at once showed the supposed diseased mass to consist of enlarged uterus. Further examination proved that there was nothing abnormal about the uterus, except its great size. In fact, it was a case where the organ had apparently remained nearly undiminished after delivery, probably from the puerperal attack arresting the usual progress of its absorption and diminution. It decreased rapidly under leeches and other local antiphlogistic treatment."

On November 1, 1871, Dr. Snow showed the Obstetrical Society of London the uterus and appendages of a woman, aged thirty-eight, who died from convulsions during a short illness of typhus fever. She had been the mother of several children in quick succession;

<sup>1</sup> Read before the Obstetrical Society of Boston, January 14, 1882.

<sup>2</sup> Diseases of Women, page 313.

had been an invalid for several years, etc. The uterus presented one of those forms of enlargement that are apparently caused by an arrest of those processes which reduce the organ to the unimpregnated condition after impregnation, and restore the inner surface to its original state, etc. The following conclusions were arrived at after a careful microscopical examination of the uterus:—

(1.) The essential condition of the organ consisted in the elements of the different tissues retaining a portion of the natural enlargement consequent upon impregnation. But this enlargement was more due to the increased size and amount of the soft tissue present in the walls of the uterus, as well as at the internal surface, than to the increased size of the contractile fibre-cells.

(2.) Although the blood-vessels were large and loaded with fluid blood, yet there was no evidence to prove that any morbid process, similar to inflammation or otherwise, had at any time been present. Indeed, everything indicated an opposite conclusion.

(3.) The whole of the blood-vessels to the minute capillary network at the inner surface formed one continuous system, though the character of the distribution changed towards the inner surface, and considering there is no division in the uterine walls to justify the description of an internal mucous membrane, this distribution appears to offer a strong argument against the idea that the internal surface could be the seat of inflammation independent of the other portion.

(4.) The pulpy condition at the inner surface, with the loaded state of the blood-vessels throughout, appear to afford a probable explanation of the frequent and severe hemorrhages which attend similar enlargements.

(5.) This uterus, which presented in a marked manner all the characters attributed to the so-called inflammatory ulceration, is one evidence amongst many of the extreme fallacy of such statements. There was no evidence of any inflammatory action ever having existed, nor was there the least abrasion or destruction of surface anywhere. The tissue of the inner surface of the neck looking red and soft, and bounded by a distinct margin at the junction of the mucous membrane of the vagina, is no evidence of the presence of ulceration.

The uterus to which the foregoing details pertained was three and a half inches in length, two and a fourth inches across the fundus, the walls one and three eighths of an inch thick, and the uterine cavity full three inches long. The os was large, admitted easily the end of the finger; its lips large, of a strong violet-blue color, and projected half an inch into the vagina. Six or eight, small pin head in size, cysts were found at the inner os.

Although there may be influences which favor areolar hyperplasia in the uterus of a woman who has never been pregnant, such as the presence of fibrous growths in its walls; excessive sexual relations, as with prostitutes; and, I dare say, imperfect coition to prevent impregnation, etc., yet these play an unimportant part in its causation as compared with utero-gestation.

In this connection, Thomas<sup>1</sup> summarizes his conclusions thus:—

(1.) "The condition ordinarily styled chronic metritis consists in an enlargement due to hypergenesis of

its tissues, especially of its connective tissue, which induces nervous irritability, and is accompanied by congestion.

(2.) "Decidedly the most frequent source of this state is interference with involution of the puerperal uterus. A very large proportion of the cases of so-called chronic parenchymatous metritis are really later stages of subinvolution.

(3.) "Areolar hyperplasia is often induced in a uterus which has once undergone the development of pregnancy; by displacement, endometritis, and other conditions inducing persistent hyperæmia.

(4.) "The same influence may possibly produce it in the multiparous uterus, most frequently they do so in the neck, but such a result is exceedingly infrequent.

(5.) "However produced, the condition is one of vice of nutrition engendering hyperplasia of connective tissue as its most striking feature, and, although attended by many of the signs and symptoms of inflammation, it in no way partakes of the character of that process."

Subinvolution of the uterus is a disorder frequently met with in practice, and nearly always in women who have undergone utero-gestation. An exciting cause may be ascertained in many cases; there may be a history of septicæmia, or pelvic inflammation; the presence of laceration of the cervix uteri, or perineum; or a generally feeble condition; or organic disease of some kind, especially of the heart and liver. As already stated, this affection was formerly regarded as a chronic inflammation of the uterine tissues, and described at great length as such by writers on uterine diseases. Although we may not have yet arrived at the true nature of its pathology, sufficient has been learned to entirely upset our former notions regarding its frequency, behavior, and treatment.

Subjects of subinvolution complain of various discomforts, chief among which are too frequent and profuse menstruation, leucorrhœa, dragging sensations about the hypogastrium, and backache, dysuria, disordered digestion, depression of spirits, exhaustion, etc.

Examination of the pelvic organs finds the uterus heavy and lying low, often retroverted, sometimes anteverted, tender at the junction of the body with the cervix, os patulous admitting the first joint of the index finger, margins rough, cervix often fissured. The uterine cavity generally measures from three and a half to four and a half inches, sometimes more, in depth. Probing the cavity when there is a displacement gives, oftentimes, much pain, and is followed sometimes with the escape of blood from the uterus. Specular examination discloses great congestion of the cervix, vagina, and vulva.

In this connection we must always bear in mind that there are cases which simulate the conditions existing in this disorder, but caused by an entirely different disease; for example, a uterus with a polypus within its cavity, or a fibrous growth in its walls, might give origin to symptoms similar to these I have described.

Subinvolution or areolar hyperplasia of the uterus has proved itself obstinate to treatment, although great relief may be afforded the sufferer in every case. When of long duration, complicated with displacement and its effects, with profuse menorrhagia, indicating engorgement of the lining membrane of the uterus, with eroded cervix, when the general system, but especially the nervous, has suffered from long continued

<sup>1</sup> Diseases of Women, page 320.

local irritation, the restoration of the womb to a comparatively healthy state is generally slow, and the results of treatment at times discouraging.

The treatment consists in removing the obvious causes so far as they can be ascertained. To recapitulate:—

After a careful examination the uterus may be found displaced, engorgement of its lining membrane may be present, as shown by the escape of blood on probing its cavity; there may be granular erosion or cystic disease of the cervix and endocervix; there may be laceration of the neck of the womb, — and the cavity will measure an inch or two more than that of the healthy uterus. All this may be present in a case which commenced its pathological career as one of sub-involution, which, had there no complications ensued, would have probably given but little discomfort to the patient.

The following is a plan of the treatment pursued by me under the above circumstances:—

(1.) To rectify the displacement which, if it existed for some time, has given rise to endometritis and increased vascular engorgement.

(2.) To reduce vascular turgidity by local bleeding, repeated at intervals from seven to ten days.

(4.) Menorrhagia usually dependent on an altered state of the endometrium, relieved by the use of the wire curette; so, also, the morbidly altered cervical glands.

(4.) To promote healthy and absorptive action of the endometrium and cervix, Churchill's tincture of iodine is applied by means of a probe covered with absorbent cotton, or injected into the uterus by aid of a double catheter. This may be used once a week.

(5.) Daily vaginal enemata of water at a temperature of 115° F.

(6.) If there be deep and gaping laceration of the cervix, repair by plastic operation as indicated; although what appears to be a pretty deep fissure on first examination becomes shallow and insignificant after a course of treatment.

(7.) General constitutional treatment. This must vary with the conditions present, but generally a mixture containing sulphate of iron, dilute sulphuric acid, and sulphate of magnesia with ergot, is given to strengthen the system and diminish local plethora.

(8.) Suitable diet and clothing.

(9.) I have not ordered rest in the treatment of these cases, provided patients could take exercise, for I have found less chronic invalidism accompany uterine disease generally where the subjects of them were advised to go into the open air as much as possible, and to avoid passing their days on the bed or sofa.

It is with the hope that this important condition of the pelvic organs of woman will receive from this Society the consideration which it deserves that these observations of myself and others have been related.

—The commencement exercises of the Chicago medical colleges are over. Rush College graduated, February 21st, a class of 179. Honorary degrees were conferred upon J. Milner Fothergill, of London, and Giovanni Paladino, of Naples.

The commencement exercises of the Woman's College occurred February 28th, and a class of twenty-three was graduated.

# A CASE OF PULMONARY EMBOLISM ON THE NINTH DAY AFTER DELIVERY. RECOVERY.<sup>1</sup>

BY C. E. STEDMAN, M. D.

Mrs. W., aged twenty-nine, was delivered of her third boy on the 25th of November, after a short and normal labor. She was a healthy and active young lady, but had suffered much during this pregnancy, at first from nausea, latterly from fleeting pains and sleeplessness, and was apprehensive of the issue. There was no albuminuria, and little loss of blood after delivery. Having been made comfortable, she fell asleep, and enjoyed a rest to which she had been a stranger for months. Her appetite was good, the milk abundant, the lochia normal, and convalescence speedy. She seemed to make the best puerperal case of the year. But on the forenoon of the ninth day, as I stopped at the house to make a farewell visit, I was surprised to be hastily called indoors, and told that the patient had had a violent convulsion. On entering the chamber and seeing her face I thought she was dead, such was the ashy hue and cadaveric expression of the features. She was nearly pulseless, her lips white, the respiration rapid and shallow. The nurse, who had seen eclampsia, syncope, apoplexy, and hysteria, was badly frightened, for she said the symptoms were different from any she had encountered. The patient had been helped to a cabinet by the bedside, and had attempted without success, but without straining, to have a movement of the bowels. She was then helped by the nurse to bed, and while sitting on its edge suddenly turned livid, stillly extended her arms and fingers, with her eyes staring, teeth set, face purple, as she gasped and struggled for breath, without being able to speak, for several minutes; the muscular tension then relaxed, and she tried to tear open her dress at the neck, breathing very quickly. This state continued half an hour, when, on being laid down in bed, she turned deadly pale, again threw her hands and arms stiffly out, the struggle for breath was renewed, and she appeared to be dying. In this state I found her, three quarters of an hour after the seizure. Finding that she could swallow, I gave her some sherry, which stood near, with a spoon, and by the time she had taken a second glass a faint color returned, respiration was perceptible, and rapid, thready pulse could be felt. She whispered that I was not to leave her, and complained of oppression on the chest; her hands, legs, and face were deathly cold, and the pupils dilated widely. An hour after the pulse was wiry, 130, respirations 40, temperature 98.2° F. All that could be heard through the stethoscope was rapid and tumultuous cardiac action with blowing respiration at the summits of both lungs. She rallied during the day, took milk and brandy, and in the evening the pulse had fallen to 125, the respirations to 32, and the temperature remained normal. She said she felt as if an iron weight lay on the upper part of her chest and bore backwards to between the shoulder blades, and told me, "I know what it was, it was death." During the day there were two or three moderate accessions of dyspnoea. The next day report was made of a good night; the pulse 112, and respiration 28. She was kept perfectly quiet, and took milk and wine in good quantities; at one o'clock there was a tendency to recurrence of dyspnoea; at five she was resting, and com-

<sup>1</sup> Read at the meeting of the Obstetrical Society of Boston held January 14, 1882.

plained of pain in the shoulders; pulse 108; respiration 28; temperature 100.2° F. The temperature remained elevated for one or two evenings, and then subsided till the pulse and respiration became normal, on the seventh day after the attack.

Her mother told me that her sister (the patient's aunt) died suddenly with symptoms resembling my patient's, three weeks after labor.

The awful suddenness of this attack, the date after labor of its occurrence, the struggle for breath, the livid face succeeded by pallor, the thready pulse, the short breath, the sense of suffocation and impending death, the recurrences of dyspnoea, point to but one diagnosis, that of pulmonary obstruction. Her recovery made me doubt my diagnosis, and I could find nothing that was reassuring till I consulted Barker and Playfair, whose chapters on this subject are the fullest and most satisfactory treatment of it which I can find. I therefore freely quote from the latter as follows:—

Playfair asks, "Have we any ground for supposing that there is a possibility of recovery after symptoms of pulmonary obstruction have declared themselves? That such a result must be of extreme rarity is beyond question, but I have little doubt that in some few cases, entirely inexplicable on any other hypothesis, life is prolonged until the coagulum is absorbed and the pulmonary circulation restored. In order to admit of this it is of course essential that the obstruction be not sufficient to prevent the passage of a certain quantity of blood to the lungs to carry on the vital functions. The history of many cases tends to show that the obstructing clot was present for a considerable time before death, and that it was only when some sudden exertion was made, such as rising from bed or the like, calling for an increased supply of blood, which could not pass through the occluded arteries, that fatal symptoms manifested themselves. This was long ago pointed out by Paget, who says, 'the case proves that in certain circumstances a great part of the pulmonary circulation may be arrested in the course of a week (or a few days more or less) without immediate danger to life or any indication of what had happened.' And after referring to some illustrative cases, yet in all these cases the characters of the clots by which the pulmonary arteries were obstructed showed plainly that they had been a week or more in the process of formation. If we admit the possibility of life for a certain time, we must, I think, also admit the possibility, in a few rare cases, of eventual complete recovery. What is required is time for the absorption of the clot. In the peripheral venous circulation coagula are constantly removed by absorption. So strong, indeed, is the tendency to this that Humphrey observes with regard to it, 'It appears that the blood is almost sure to revert to its natural channel in process of time.' If, then, the obstruction be only partial, if sufficient blood pass to keep the patient alive, and a sudden supply of oxygenated blood is not demanded by any exertion which the embarrassed circulation is unable to meet, it is not inconceivable that the patient may live until the obstruction is removed."<sup>1</sup>

Barker gives two cases of recovery, one in a primipara, who had dismal forebodings about the issue of her confinement, having lost her mother and two sisters from post-partum hemorrhage. She lost no more than a normal amount of blood, but in an hour and a

half after delivery she collapsed with symptoms of pulmonary embolism. It was eight hours before she rallied, but ultimately recovered.

Another patient, four or five hours after the birth of twins, was asphyxiated. She recovered, but subsequently had phlegmasia dolens.

The cases which Playfair gives as recoveries from this condition, I have condensed as follows:—

The first occurred in a delicate primipara, after an easy labor, followed by flooding profuse enough to weaken her. The alarming dyspnoea came on the seventh day. For several days she remained in a critical condition, the most trifling exertion bringing on the attacks; a slight blowing murmur was heard at the base of the heart, and then disappeared. For two months she remained in this state, any attempt at sitting up in bed bringing on the embarrassed respiration; during all this time it was found necessary to administer stimulants profusely to ward off the attacks, but she recovered completely.

The second was in a woman of forty-four, the mother of twelve children. On the eleventh day after confinement she went to bed feeling well, with no local or general symptoms. At 3.30 A. M. she was sitting up in bed when she was suddenly attacked with an indescribable sense of oppression in the chest, and fell back in a semi-unconscious state, gasping for breath; she remained in a very critical condition with the same symptoms of embarrassed respiration for three days, when they gradually ceased. Two days after the attack phlegmasia dolens of the left leg supervened, and remained for several months.

A primipara, aged twenty-four, thirty hours after delivery complained of great weakness and dyspnoea; this was alleviated, but on the ninth day, after sudden exertion, the dyspnoea returned, and continued fourteen days, the least excitement or talking inducing the most aggravated dyspnoea, which threatened almost instant death. Air entered the lungs freely in front and behind; immediately over the site of the pulmonary arteries there was a distinct, harsh, rasping murmur confined to a very limited space, and not propagated either upwards or downwards; the heart sounds were feeble and tumultuous. Though a fatal prognosis had been made she slowly recovered, and six weeks later the murmur had disappeared.

Playfair gives a fourth, which proved fatal although the local symptoms had disappeared.

A primipara flooded severely from an adherent placenta, the dyspnoea attacking on the fourteenth day; at the fourth interspace, near the sternum, there was a loud, blowing, systolic murmur, not before present; she had oedema of the neck, and two days after the chest symptoms phlegmasia dolens developed in the right leg. She had frightful attacks of dyspnoea in which she called for stimulus, which always relieved. The seizures became less frequent, and after the twenty-fifth day she had no more. She, however, sunk, and died of exhaustion forty-four days after delivery.

All but one of these cases differ from that I have reported in having flooding before or phlegmasia dolens after the attack. Mrs. W. had no other weakening influence than a troublesome pregnancy which prevented sleep, which she fully made up for after the baby was born. Her speedy convalescence was exceptional, and the recurrences of dyspnoea were few and trifling.

This is the only case of the kind I have seen in the

<sup>1</sup> Vol. ii., p. 340.

lying-in room, but in two patients who died after placenta prævia, where hemorrhage was controlled by treatment, and no excessive amount of blood had been lost, I am convinced that the issue, preceded by dyspnoea, and at the time (ten or more years ago) ascribed to shock, was due to heart-clot. In examining records of typhoid fever in the City Hospital there is found one example of sudden death in which the diagnosis of pulmonary embolism was confirmed by autopsy.

Sudden death in labor is described by Denman, Chevalier, Robert, and others, and attributed to various causes. "Dr. Meigs, of Philadelphia, was the first to point out, in 1849, the spontaneous coagulation of the blood in the right side of the heart and pulmonary arteries as a cause of sudden death in the puerperal state, but Paget had written of the lesion in other than lying-in women in 1845. In 1855 Hecker attributed most of these cases to embolism proper, and since that date most authors have taken the same view, believing that spontaneous coagulation occurs only in exceptional cases, such as those in which, on account of some obstruction in the lung, or in the debility of the last few hours before death, coagula form in the smaller ramifications of the pulmonary arteries, and gradually creep backwards towards the heart."

"A case related by Richardson in his clinical essays was that of a man who, for weeks, had symptoms precisely similar to those described by Playfair. In one of his agonizing attacks he died, and after death it was found that a fibrinous band extended into the pulmonary artery. This observation proves to a certainty that life may continue for weeks after the deposition of a coagulum, and, moreover, this condition was precisely what we should anticipate, since, of course, the obstructing coagulum must necessarily be small, otherwise the vital functions would be immediately arrested."

Playfair considers the strongest argument in favor of the spontaneous origin of pulmonary thrombosis to be one which he originally pointed out in a series of papers on Thrombosis and Embolism of the Pulmonary Artery as a Cause of Death in the Puerperal State. "He then showed, from a careful analysis of twenty-five cases of sudden death after delivery, in which accurate post-mortem examination had been made, that cases of spontaneous thrombosis and true embolism may be divided from each other by a clear line of demarcation depending on the period after delivery at which the fatal result occurs. In seven out of these twenty-five cases there was distinct evidence of true embolism, and in these the death occurred at a remote period after delivery, in none before the nineteenth day. This contrasts remarkably with the cases in which the post-mortem examination afforded no evidence of embolism. These amounted to fifteen out of the twenty-five, and in all of them, with one exception, death occurred before the fourteenth day, often on the second or third. The reason of this seems to be that in the former time is required to admit of degenerative changes taking place in the deposited fibrin leading to separation of an embolus, while in the latter the thrombosis corresponds in time and to a great extent, no doubt, also, in cause, to the original peripheral thrombosis, from which, in the former, the embolus was derived. Another clinical fact points in the same direction. In one or two cases distinct signs of pulmonary obstruction have shown themselves without proving immediately fatal, and shortly afterwards peripheral thrombosis, as evinced by phlegmasia dolens

of one extremity, has commenced. Here the peripheral thrombosis obviously followed the central, both being produced by identical causes, and the order of events necessary to uphold the purely embolic theory was reversed."

The most satisfactory discussion of these points by authorities at my command I find in Barker, Simpson, and Playfair. I note nothing about it in Ramsbotham or the first edition of Leishman. Schroeder dismisses it in a few lines on sudden death after labor.

The opinion I formed of my patient was that a small embolus was picked up from the uterine sinuses, carried into the right side of the heart, and at the pulmonary valve stopping the circulation and causing lividity, the clot passed on into the artery at its bifurcation, when the patient became pale, and nearly ceased breathing; rallied by the stimulus, and respiration re-established, the body was swept further on and absorbed in less than forty-eight hours. It may be of comfort to some practitioner, whose patient does not die instantly of an attack like the one reported, to know that there is a chance of life, however weak.

## THE FIRST MEDICAL SCHOOL IN AMERICA; AN HISTORICAL ITEM.

BY FRANCIS H. BROWN, M. D.

IN the report of a recent meeting of the Massachusetts Historical Society<sup>1</sup> it was noted that inquiry had been made concerning a "certain gentleman of Boston" who in 1739 liberally offered to establish a professorship of medicine "in this Province, and who deserves the honor of having been the first promoter of medical education in America," even though his plans appear at the time to have been fruitless.

By reference to the journal of the House of Representatives for July 7, 1739, one may find this record: "Information being given to the House by the Member from Worcester, that a certain gentleman of the town of Boston, well disposed for the Encouragement and Support of a Professor of Physick within this Province, and that for good Purpose would cheerfully contribute out of his own Estate a considerable Sum of Money, provided this Court will join in making a Grant of Lands, or other wise establish a good Fund for the valuable Ends aforesaid; and the same being considered:

"Ordered, That the Members of Boston, Charlestown, Roxbury, and Chelsea, be a committee to treat with the said Gentleman, hear him on his Proposals, and report their Opinion of what may be proper to be done for the encouragement of so good a Scheme."

Whether the gentleman indicated appeared before the committee cannot be ascertained; but no action was taken on his suggestion, certainly during that session of the General Court.

The learned gentleman who propounded this inquiry is in error in considering this the first attempt at a medical school in the provinces. In making investigations regarding the history of medicine in America previous to 1700, and especially in reference to biographical memoranda concerning the earliest physicians of Boston and its neighborhood, I find in the first general letter issued by the Massachusetts Bay Company to Endicott, under date of April 17, 1629, the following passage:—

<sup>1</sup> Boston Daily Advertiser, March 9, 1882.

"We have entertained Lambert Wilson, surgeon, to remain with you in the service of the Plantation: with whom we are agreed that he shall serve this Company and the other planters that live in the Plantation, for three years, and in that time apply himself to cure not only of such as came from hence for the general and particular accounts, but also for the Indians, as from time to time he shall be directed by yourself or your successor and the rest of the Council. And moreover he is to educate and instruct in his art one or more youths, such as you and the said Council shall appoint, that may be helpful to him, and, if occasion serve, succeed him in the Plantation: which youth or youths, fit to learn that profession, let be placed with him; of which Mr. Hugesson's son, if his father approve thereof, may be one, the rather because he has been trained up in literature; but if not he, then such other as you shall judge fittest."

Young, in his *Massachusetts Bay Chronicles*,<sup>1</sup> very truly says:—

"We have here the embryo of a medical school, undoubtedly the first contemplated on the Continent of America."

No record, however, exists of the success of this school, or of that to which reference is made in the letter to the Historical Society; but as an historical fact the *attempt* to found a medical school in 1629 has the precedence of the other by one hundred and ten years.

## PROGRESS IN GENITO-URINARY SURGERY.

BY ARNER POST, M. D.

### NEPHRO-LITHOTOMY.

A CASE of removal of a calculus from an otherwise healthy kidney was reported to the Clinical Society, of London, by Mr. Henry Morris.<sup>2</sup> By the term nephro-lithotomy Mr. Morris means the removal, through a lumbar incision, of a renal calculus from a kidney in which the pelvis is not dilated and which, but for the presence of the stone, is presumably healthy.

This operation is to be distinguished from the numerous cases in which the kidney is cut for the evacuation of fluid accumulated within it, whether as the result of a renal calculus, of tubercular disease, or some other cause, and to which, from ancient times, the name nephro-lithotomy has been applied, as well as from those cases, also numerous, in which a stone has been removed after it has been detected through a sinus in the loin.

The opinion of writers has been universally adverse to the attempt to remove a stone from the kidney unless it could be reached through a distended pelvis, fatal hæmorrhage being feared if the excreting substance of the kidney was cut or torn. The case described by Mr. Morris proves the feasibility of the operation.

A servant girl, aged nineteen, had for eight years been subject at times to pain in her right side, accompanied occasionally with a feeling of sickness and even actual vomiting. There was tenderness but no swelling in the right loin.

No relief being gained from treatment, and employ-

ment aggravating her symptoms, chloroform was administered and the right kidney exposed through an oblique lumbar incision. The right index finger was then passed over the posterior surface of the kidney and at once detected something faintly projecting from the renal substance near the hilus. The renal substance was incised near the spot with a probe-pointed bistoury and a mulberry calculus of triangular shape, weighing thirty-one grains, was extracted by means of a scooping movement of the finger tip. There was no hæmorrhage at any stage of the operation. The upper end of the ureter was not dilated. No attempt was made to examine the front side of the kidney.

Urine ceased to flow through the wound in less than three months, and the patient made a good recovery. Thus the operation shows that a stone may be removed from a healthy kidney by incision without serious hæmorrhage, and without greater risk than is warranted by the sufferings and disability which the operation was designed to remove.

Mr. Morris propounded four questions necessary to be considered before the success of one case is allowed to influence treatment in others. (1.) Can the diagnosis as to the disease and the organ affected be made with certainty? (2.) What are the prospects of being able to complete the operation when a stone is found? (3.) What are the dangers of the operation? (4.) What is the best result which can be hoped for from the operation if successful?

In the discussion which followed Mr. Barker gave the history of a case in which he had cut down upon the kidney and incised the organ, but the calculus was of large size and branched. He removed part of it and some pus escaped. Unfortunately a large portion of the calculus was left behind and its extraction being difficult he was led to attempt the removal of the whole organ, but, unable to remove it perfectly, he found it easier to extract the calculus, which he accordingly did. In this case the diagnosis rested between renal calculus and tubercular disease. By passing a needle through the loin he struck the stone, and he believed this the first case in which a renal calculus had thus been sounded through the loin.

Mr. Bryant supported Mr. Morris as to the advisability of performing the operation. For as it was not one of great difficulty, was not always of great simplicity and should not be undertaken without grave consideration. Granting the diagnosis of stone in the kidney and the want of relief in spite of medical skill, then there would be but little hesitation in the surgeon's cutting down to remove the calculus. But all knew of cases where a calculus settles down and the patient lives for years no longer troubled by it; such cases make one hesitate in arguing in favor of the operation. The method of diagnosis alluded to by Mr. Barker was interesting, but he doubted the expediency of such attempts in view of the important structures in the neighborhood which might be injured. To clear up a doubt it might be expedient to use these means.

Mr. Heath, without wishing to detract from the value of the operation, considered that it was done under remarkably favorable circumstances. The patient was young and the stone presented on the surface so as to be readily identified. As it protruded the renal substance there was not much of the organ incised. Mr. Barker had opened the kidney in his case by means of Paquelin's cautery. Mr. Heath thought a

<sup>1</sup> Page 165.

<sup>2</sup> The *Lancet*, October 30, 1880. Clinical Society's Transactions, vol. xiv., p. 9.

puncture might be made in the loin for the diagnosis of calculus without any risk; it only required a fine aspirating needle and the large vessels were far out of danger. In the case of a small calculus — as in Mr. Morris's case — it would be very fortunate if detection could be effected in this way.

Mr. Morris agreed with Mr. Heath that his case was a remarkably fortunate one from the small size of the stone and its projection; but there was considerable incision and laceration of the kidney in the extraction of the stone.

Dawson had detected a stone by puncture through the loin. If acupuncture were used it would be far more certain of success if applied to the kidney itself after an incision in the loin.

During the discussion Mr. Barker mentioned a case published in the *Berliner Med. Wochenschr.* by Peters. There were symptoms of renal calculus which the author verified by passing a trocar and canula into the kidney and striking a stone. Unwilling to subject the patient to the risks involved in cutting down onto the kidney, he left the canula *in situ* for some time, and afterwards dilated the wound by tents until the sinus was large enough to admit the finger. He then passed in the lithotrite and crushed the stone before removing it. The fistula healed up completely.

Within the past few weeks Dr. Bardenheuer,<sup>1</sup> of Cologne, has performed the operation for complete suppression of urine, with success. The patient had been long in the hospital; her urethral sphincter had been divided to secure incontinence as a relief for certain bladder symptoms, and the left kidney had been destroyed by suppuration. On the 8th of February, 1882, she was unable to pass any urine; the bladder contained only a little slime and a small stone; pain in the region of the right kidney, radiating towards the bladder, set in accompanied by nausea. The following day complete anuria continued, and the accompanying symptoms had increased. As death was the only possible result, Bardenheuer resolved to attempt operative measures. Accordingly, a flap was raised over the region of the kidney, the fatty capsule divided, and the kidney easily reached. To gain the pelvis and the ureter, the anterior portion of the organ was gradually loosened from the surrounding fat. At the moment when the operator reached the hilus of the kidney a stone was felt, which slipped back under the operator's fingers into the pelvis. Immediately a stream of urine shot from the urethra; the communication between bladder and kidney was momentarily reestablished. To extract the stone the kidney and ureter were further loosened from the surrounding connective tissue until it was possible to turn the kidney upon itself so that the hilus presented at the bottom of the wound. The stone, which had again fallen into the beginning of the ureter, was then fixed by two fingers of the left hand, the wall of the ureter divided upon it, and a smooth stone, about the size of a bean, was thus extracted. Four small stones were discovered by the finger in the pelvis of the kidney, and removed. Stitches were taken in the ureter, and the external wound stuffed lightly with antiseptic gauze. For three days the patient did fairly well, urine escaping from the wound only. On the fourth a chill supervened, and finally it became necessary to abandon the attempt to reestablish the normal course of the urine; the ureter was divided and the cut end brought out

through the wound in the loin. The last report from the patient (March 12th) reads, "Free from pain, and partially convalescent. The part of wound over which urine does not flow is clean."

#### DIAGNOSIS OF RENAL CALCULUS.

The majority of urinary calculi are primarily formed in the pelvis of the kidney. Even in new-born infants urinary concretions have been met with in that organ. The demonstration of the feasibility of operations for the removal of renal calculi gives additional interest to the study of the surgical disorders of the kidney and to systematic attempts at accurate diagnosis. In ordinary text-books little attempt is made to group the symptoms attending the presence of stone in the kidney. Dr. Coupland has published a clinical lecture<sup>2</sup> in which he has given the history and grouped the symptoms of a single case in which he diagnosed renal calculus and advised the operative interference which resulted in the brilliant operation of Mr. Morris's mentioned above. Although no new symptoms are given, the subject is so important that Dr. Coupland's recapitulation may prove of interest and possibly benefit. After giving the general history of the patient, he thus summarizes her symptoms:—

"Localized pain in the region of the right kidney, sometimes passing downwards to the thigh or else across the back, occurring paroxysmally more or less for ten years, with increasing frequency and severity during the past two years, notably influenced by movement and active occupation — so much that her ordinary duties were hampered, and life rendered miserable, by the attacks. She used to say that as long as she was perfectly at rest she felt no pain; but this was not strictly accurate, for sometimes her nights were disturbed by its occurrence.

"Then, bearing some relation to this, inasmuch as it was always at its height, when she came into the hospital, there was hæmaturia; and hæmaturia of undoubtedly renal origin. The blood was diffused equally throughout the urine; it came from the pelvis or from the kidney itself, and the local pain and tenderness pointed to the right kidney as its source.

"*Pain in the kidney, or nephralgia*, may owe its existence to many causes. The first and simplest is that which is accompanied by a loaded state of urine, where the imperfect oxidation of nitrogenous materials taken in by the food stops short of the formation of urea, and leads to a greater excretion than normal of lithic acid and its derivatives, of which oxalic acid has been proved to be one. In that case, as a rule, the pain is of a dull, aching character in both loins, the digestion is deranged, and the bowels are torpid. Undoubtedly such a condition may be the precursor of calculous formations, and it is intimately related to the gouty state. But in it the urine is loaded with lithates, and hæmaturia is not a symptom.

"The presence of *hæmaturia* points, indeed, to a more advanced affection, and, in association with the unilateral character of the nephralgia, we must look to lesion of one kidney to account for it.

"I think we may expunge all idea of a simple *neuralgia* of this kidney or its surroundings, although I would not deny the existence of such an affection. But the passage of blood takes the case out of that category.

"On the other hand, the curious and interesting dis-

<sup>1</sup> Centralblatt für Chirurgie, No. 12 (March 12), 1882.

<sup>2</sup> Medical Times and Gazette, February 18, 1882.

ease called '*paroxysmal hæmaturia*' must not be considered at all in connection with this case. For, although, to be sure, the presence of blood in the urine was most paroxysmal and intermittent in its occurrence, yet it was *blood*—actual corpuscles, and not mere hæmatin—that appeared; not to mention the fact that no other symptoms or any other facts in the history pointed to this affection.

"*Congestion of the kidney* there undoubtedly was; but mark that it was congestion of *one* kidney only, and if there was any actual nephritis (of which we have no clear evidence) it was unilateral and required a local cause.

"It seems, then, that we are narrowed to organic causes affecting the right kidney—limited, in fact, to new growths, or to calculus.

"The pain and the hæmaturia are consistent with the diagnosis of a *new growth*—say a papillary villous growth in the pelvis of the organ; for a cancerous tumor it could not be, looking at the nutrition of the girl. But are the facts of the case, when analyzed, consistent with it? Assuredly not. The long duration of the symptoms, and, above all, the very intermittent character of the discharge of blood,—a discharge distinctly related to movement,—put it out of court.

"So that you see the case presented symptoms which could hardly be well explained except on the view of *renal calculus*. They were symptoms excited by the mechanical effects of the stone."

Before asking the surgeon to make an exploratory incision Mr. Coupland attempted to examine the kidney by passing the hand into the rectum, but in spite of steady and prolonged pressure found it impossible and desisted from the attempt.

#### WOUNDS OF THE BLADDER.

Wounds of the bladder are among the rarest of accidents. Their severity varies with the character of the injury. They are usually divided into two classes as to their connection with injury of the peritoneum, into extra and intra peritoneal wounds. The situation of such injuries has been most carefully studied by Bartels,<sup>1</sup> who concludes that: "These wounds are certainly fatal when they involve the peritoneum, large vessels, or the hip-joint.

The proper treatment of such cases, particularly of intraperitoneal wounds, has been within the past few years a subject for grave discussion. The great advance in surgery commensurate with the advance in ovariotomy points to the possibility of directly approaching the bladder through the abdominal walls. Three cases are recorded in which the peritoneal cavity was thus opened to reach a ruptured bladder. One recovered, that of Walter of Pittsburgh, two were fatal, those of Willett and Heath. The experience of Mr. Heath led him to say that in future he should prefer the more conservative practice of draining the peritoneum through the bladder by catheterism or perineal cystostomy if necessary.

Vincent<sup>2</sup> calls in question the truth of the conclusions reached by Bartels and the inference drawn by Heath, and has devoted much time and labor to the elucidation of the subject. His paper is a long one, and reviews critically all previous experiences on the subject and gives the details of his own numerous and

carefully conducted experiments. These experiments were made upon twenty-nine dogs, and his conclusions and applications are as follows:—

The insufficiency of other means than abdominal section, in intraperitoneal wounds of the bladder followed by an abundant outflow of urine into the peritoneal cavity, is shown by statistics; no other means permits the proper appreciation of the extent of the wound nor of its complications, caused by the concomitant wounding of other viscera or of the pelvic skeleton; no other course permits the treatment of such complications by proper means, as, for example, enterorrhaphy, extraction of bony fragments, etc.; no other prevents further extravasation of blood and urine or permits cleansing the peritoneal cavity of urine already extravasated.

Dwelling at some length upon the very evident advantages of peritoneal section in such cases, he continues: "Antiseptic surgery justifies this method of operation, if otherwise rational, by the numerous successes which it has procured in abdominal surgery; so much the more since death is almost certain if one does nothing or relies upon other means than laparotomy."

In the successful case of Walter of Pittsburgh, one circumstance ought to be made prominent: Walter operated ten hours only after the accident, that is to say, before the peritonitis had become marked, before the urinary intoxication was very far advanced. Willett and Heath, who failed, operated, the one thirty, the other forty hours after the rupture. It is to be supposed that the difference in the time which had elapsed from the accident to the operation explains better the difference in the results than any difference in the omission or the practice of the vesical suture.

From the analysis of these three known cases the following conclusion can be drawn: It is of the utmost importance to have recourse to laparotomy as soon as possible, and, secondly, that the suture of the bladder receive particular care, that it may not fail too soon.

Experience shows that intraperitoneal solutions of continuity of the bladder are capable of uniting by first intention with a good suture, and even spontaneously, in certain entirely exceptional conditions upon which one cannot count.

Reunion takes place with great rapidity in all the coats of the bladder walls, except the epithelial layer of the mucous coat, but most quickly by the union of the peritoneal covering in which proliferation commences a few seconds after coaptation. One ought, then, to have special reference to this coat in the establishment of suture.

• To obtain a solid suture that shall resist vesical tenesmus, that shall endure the active contractions and passive expansions of the bladder, the following points must be observed: to place the stitches close together, to avoid making them penetrate through the mucous coat, to bring closely together large surfaces of the peritoneal covering, doubling and superposing lines of sutures.

In making the suture as recommended one need not fear the appearance of urinary fistula, either between or around the stitches, an accident which may follow when the stitches are too far apart or penetrate the mucous coat. Nor need one fear the formation of lithic concretions about the threads following their fall into the bladder, since the threads, being only superficial to the organ, do not fall into the interior. If they detach themselves they become encysted by means of the exudation which they provoke; threads, whether

<sup>1</sup> Langenbeck's Archiv für klin. Chir., Bd. xxii.

<sup>2</sup> Revue de Chirurgie, vii, and viii., 1881.

organic or metallic, ought to be cut as short as possible to leave the smallest possible foreign body in the peritoneal cavity. Ordinary carbolized silk should be preferred when but a single row of sutures is used; when a double row is made catgut can be used for the deeper sutures without danger of its too early absorption. Before closing the abdomen it is advisable to assure one's self of the proper mechanical condition by injecting into the bladder a colored but indifferent fluid.

Gum-shot wounds may be closed like other wounds, cutting away, if necessary, the bruised edges of the perforation until a point is reached that bleeds; edges should be refreshed also in cases in which the suture is somewhat delayed, as in other solutions of continuity. Even the larger portion of the bladder may be removed, with the possibility of recovery with the suture.

Capillary punctures and perforations with cutting instruments of small diameter recover spontaneously.

In general, in the experiments, immediate union has been the rule in intraperitoneal perforations of the bladder, whatever the character of the perforation, whether forcible ruptures, done by cutting instruments, or firearms, when the suture has been immediate. The operation (that is, opening the abdomen, cleansing the peritoneal cavity of blood and urine, suture of the bladder) has been followed by recovery eight hours and a half after the perforation of the bladder only, according with the clinical experiment of Walter. But practiced twenty-four hours after the perforation and later it has constantly failed, and the animals have succumbed more to urinary intoxication than to the violence of the peritonitis, agreeing with the cases of Willett and Heath.

In the first ten to twelve hours the chances of success are very great; they diminish in proportion to the time which elapses from the moment of the accident. Nevertheless, if the general condition of the patient is not too compromising it is advisable to have recourse to the operation, whatever the interval of time.

These observations of Vincent were still further exemplified in a paper read before the London International Congress, in which he detailed a second series of experiments upon rabbits, and further gave an account of a wound of the bladder occurring in an ovariectomy, in which the woman died from causes unconnected with the vesical wound, which had conducted itself favorably. Other wounds of the bladder at the hands of several surgeons, occurring similarly during ovariectomy, have favorably united, showing the soundness of the conclusions in regard to early suture. They have been reported too recently in the JOURNAL<sup>1</sup> to need repetition.

In a paper on Excisions of the Bladder,<sup>2</sup> Dr. Adolf Fischer details experiments on dogs, and arrives at conclusions very similar to those of Vincent. He believes good results to be principally dependent upon the accuracy of the suture.

#### THE PREVENTION OF PROSTATIC OBSTRUCTION.<sup>3</sup>

Mr. Reginald Harrison has been led to believe that the effects of enlarged prostate may be in great measure prevented by proper treatment. His attention was first called to the point some years ago by the case of an

elderly gentleman who had been told, years before he came under Mr. Harrison's notice, that his slight urinary troubles were the early indications of an enlarged prostate. In consequence of his alarm he never allowed a day to go by without passing a full-sized gum-elastic bougie. Post-mortem examination showed that though the middle lobe was considerably enlarged, it was deeply bisected by a canal which secured the "maintenance of the water way." In consequence of the apparently good effect of constant catheterism in this case Mr. Harrison has since advised persistent dilatation in cases in which enlargement of the prostate seemed imminent or had already commenced.

On the recognition of symptoms indicating that enlargement of the prostate has commenced, he at once urges the regular and persistent employment of the prostatic bougie. For the most effectual carrying out of this treatment he instructs the patient, as early as practicable, in the introduction of the bougie, and when he has determined the size of the instrument, requires him to use it daily, or at least thrice a week, on going to bed.

"In the employment of instruments for this purpose it is of importance that a kind should be used which is efficient, and at the same time incapable of doing harm to the parts when placed in the hands of a non-professional person of average intelligence. After many trials of different shapes and descriptions of bougies I have come to the conclusion that the instrument which best answers the purpose is the *bougie oliveaire*, of which I have selected some different sizes. The olive-shaped dilators exercise as much pressure as can be desired on the obstructing portion of the prostate, whilst by reason of the small size of the stem no tension is thrown on the most sensitive portion of the urethra, namely, the orifice.

"I have these prostatic dilators made from two to four inches longer in the stem than ordinary urethral bougies, in order that the olive portion may be fairly passed into the bladder. In this way pressure is exerted on the prostate as the expanded part passes into the bladder and again as it is withdrawn. It is very important that the instrument should be used in this way, as the dilatation exercised by the bulb on the withdrawal of the bougie corresponds with that of the urine as it is expelled from the bladder.

"At first the instrument may be passed once in forty-eight hours, subsequently twice, and in cases where the prostate has already become large I have caused it to be used night and morning with most satisfactory results.

"When the prostate is already large and the bladder is never completely emptied, I use a catheter similarly shaped to the prostatic dilator, in order that all the urine may be removed at the same time that dilatation is practiced."

In addition to mechanical measures Mr. Harrison lays stress upon certain points in the hygiene of the bladder which should be regarded by persons suffering from the earlier symptoms of enlarged prostate. These points, somewhat abridged, are as follows:—

(1.) Avoid being placed in circumstances where the bladder cannot be emptied at will.

(2.) Avoid checking perspiration by exposure to cold, thus throwing additional work on the kidneys, the constant wearing of flannel being a means to this end.

(3.) Be sparing in the use of wines or spirits exercising marked diuretic effect, either by quantity or

<sup>1</sup> Article by John Homans, M. D., the JOURNAL, February 16, 1882.

<sup>2</sup> Langenbeck's Archiv, Band xxvii., Heft 3.

<sup>3</sup> The Prevention of Stricture and of Prostatic Obstruction. R. Harrison, F. R. C. S. London: J. & A. Churchill.

quality. Diuretics have no effect in removing residual urine.

(4.) Tolerable constancy in the quantity of fluids daily consumed. A large excess over the daily quantity of fluids consumed may lead to the over-distention of a bladder hovering between competency and incompetency. The retention thus occasioned has frequently been the first step toward establishing a permanent if not a fatal condition of atony of this organ.

(5.) It is important to test the reaction of the urine from time to time. When it has become permanently alkaline prudence and comfort indicate the regular use of the catheter.

(6.) Some regularity as to the time of performing micturition should be inculcated.

## Reports of Societies.

### PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. W. SWAN, M. D., SECRETARY.

#### A CASE OF RARE FORM OF DOUBLE VAGINA.

DECEMBER 12, 1881. DR. BOARDMAN reported the case of a single woman, who sought professional advice for the relief of tenderness and itching at, and a discharge from, the vulva. In searching for the cause of these symptoms it was discovered that there was a double hymen, together with a membranous septum which extended longitudinally, from the vulva throughout the vaginal canal, and was inserted in the cul-de-sac, on the right side of the cervix, at its junction with the vagina on that side. The right canal, therefore, terminated in a blind sac, while the cervix, unusually small in size, projected within the left canal. Bimanual examination determined the fact that the fundus was normal in shape and position, and no ridge, depression, or groove could be felt on its outer surface. It was impossible, of course, without dilatation, to ascertain if any septum existed within the cervix or fundus beyond the limit of vision. The os, at any rate, was single. The patient had never been conscious of any abnormality. The catamenia had always been regular in period and quantity, and there was no dysmenorrhœa.

The left canal, the one containing the cervix, was the longer, but it appeared that, at the vulva, the finger and the speculum entered more readily within the right cavity.

The patient was informed of the condition of things, and that, in view of her approaching marriage, it became of importance from the fact that coitus was likely to take place in the blind canal, so that conception would not ensue. She appeared, however, to welcome the fact, and therefore declined to have the septum divided.

Double vagina, resulting from the imperfect union of the lower segments of Müller's ducts, occurs under a variety of forms, of which the following are the more common:—

(1.) The septum may be complete, as in the present case, but when this occurs it usually extends from the middle of the os uteri, which itself also is divided, to the vulva.

(2.) It may be partial only, extending from the cervix to a greater or less extent within the vagina; at

the same time a septum usually exists within the cervix, and sometimes extends within the fundus.

(3.) The septum may be limited to the outer portion of the vagina, in which case the os and cervix may be either single or double.

(4.) Sometimes the septum is an imperfect one, being perforated more or less with holes.

The double vagina may be associated with either the *uterus bicornis*, or the *uterus bilocularis*,—septus or subseptus. The rarity of the case presented consists in the insertion of the upper extremity of the septum on the outer aspect of the cervix, at the summit of the vagina, instead of originating at the extremity of the cervix, as a continuation of a similar septum within the latter.

DR. SINCLAIR said that these cases must be pretty rare. A few years ago a lady came to him for hæmorrhage during the catamenia. The finger discovered at the uppermost part of the vagina an extraordinary keel, half an inch deep, extending from the urethra backwards to the cervix. In the lower part of the vagina posteriorly there was a similar ridge, less marked anteriorly, but deeper and falx-shaped before it joined the cervix, dividing the posterior cul-de-sac into two cavities, the right one of which was the deeper. The patient had had a child years before, and the question occurred as to the original existence of a complete vaginal septum subsequently torn by the process of labor, but was rather negated by the fact that the partial septa presented no ragged margins. There was an eroded cervix. The entrance to the vagina was peculiar, the parts being drawn out and made tunnel-like. A search for a second opening into the uterus was successful. Dr. Sinclair remarked that this was the only instance of double uterus he had seen.

#### TUMOR, SUBSEQUENTLY ABSCESS, IN THE RIGHT ILLIAC REGION.

DR. BLAKE reported the case. [To be embodied in a future report with other cases.]

DR. ABERT questioned Dr. Blake as to the propriety of tapping in his case, and queried if the tumor were non-inflammatory whether it would not have been better to await fuller developments first.

DR. SINCLAIR suggested the propriety of first getting a few drops of fluid by means of the hypodermic syringe.

#### CELLULITIS OF THE BROAD LIGAMENT; ABSCESS-TUMOR, BECOMING SUPRAPELVIC; EXTRAPERITONEAL INCISION; RECOVERY.

DR. HOSMER reported the case, which was that of a primipara aged thirty-five. She was delivered a year ago last April. Within forty-eight hours after labor she had a chill, followed by rise in pulse and temperature, and pain and tenderness in the right groin, succeeded by a swelling, which grew quite fast, became rounded, and rose distinctly above the brim of the pelvis. Four months elapsed before this tumor began to soften. The patient went to the country, and upon her return the characteristics of abscess were found to have increased, and half a pint of pus was withdrawn by aspiration. This process was repeated several times, the last time in January, 1881. The case was then lost sight of for some months, and reappeared in the summer, when the tumor was found growing larger, but without adhesions. Dr. Hosmer then etherized the patient, and made an abdominal incision an inch and a

half long near the anterior superior spinous process and parallel with Poupart's ligament, thence deepening the opening with the finger, outside of the peritonæum, the tumor was reached and opened and a drainage tube inserted. The patient has steadily improved, but has not yet fully recovered. This attack came on soon after labor; there could be no doubt of its inflammatory character. The tumor could not be reached by rectum or vagina, and it had no close connection with the uterus itself. It was considered to be a cellulitis of the broad ligament.

Dr. ABBOT asked if gentlemen had found these tumors more frequently upon the right than the left side, and stated that the most of those he had seen were upon the right side or in the median line.

Dr. BLAKE said he thought they were not liable to come on either side with great partiality.

Dr. FIFIELD stated that his experience was that abscess was more frequent on the right side, and remarked that recent advances in anatomy had taught us some things which seemed strange, and compelled us to give up certain points to which we had clung for a long time. He did not believe that an abscess of the broad ligament ever existed. The folds of the peritonæum of the broad ligament did not contain cellular tissue, or, if any, so little that it cannot be concerned in the origin of abscess. He believed that many of the cases which came before us as abscess of the broad ligament were collections of serous fluid roofed or walled in or formed in the ischio-obturator region.

The following is the statement of Messieurs A. Guérin and Lebec as translated from the *Gazette Hebdomadaire de Médecine et Chirurgie* for the *British Medical Journal*:—

"In detaching the peritonæum from the bony walls of the true pelvis a layer of cellular tissue is pulled up with it. This layer, almost as aponeurotic as the pelvic fascia itself, they call the *fascia propria*. This layer seals up hermetically the outer extremity of the broad ligament which lies entirely below the fibrous of the broad ligament tube and the ovary.

"Another layer of dense cellular tissue is given off horizontally from the *fascia propria*, and forms a complete floor to the broad ligament. Hence the interior of this ligament is bounded by the uterus internally, by the tube above, and by the *fascia propria* below and antero-externally.

"The amount of cellular tissue between the layers of the ligament is very small, and cannot be said to constitute a 'layer.' By carefully scratching a hole in the anterior layer of the broad ligament a few grammes of colored fluid or talcum may be injected between the layers, care being taken to stop when the least resistance is felt, otherwise the fluid will force itself under the peritonæum to any extent.

"When properly injected the real cavity of the broad ligament thus produced measures a little over an inch vertically, somewhat less laterally, and not quite half an inch posteriorly. Its boundaries will be those given above as bounding the broad ligament, except that it does not extend so high as the tube, and it will be found cut off from the walls and lower part of the pelvic cavity by the *fascia propria*.

"Now, a parametric phlegmon, long held to be entirely situated between the layers of the ligament, forms a mass far bulkier than the cubic capacity of the cavity of the ligament.

"It might, however, according to older theories, be believed that abscess could actually begin between the layers of the broad ligament, and readily extend lower and lower into the pelvic cellular tissue below. Guérin and Lebec deny that this extension of suppuration can occur, as the horizontal layer of thin *fascia propria* seals up the lower limits of the ligament. The development and extension of inflammatory deposit in the pelvic cellular tissue must be traced to their sources, in short, to the lymphatic vessels.

"The lymphatics of the vagina empty into larger vessels at the level of the superior cul-de-sac, the level, in fact, of the body and the cervix of the uterus. Under the cervical mucous membrane is a very dense lymphatic plexus, which communicates with the large vessels of the upper part of the vagina. From

these united vessels one or two large trunks pass outwards towards the pelvic walls running along the base of the broad ligament, but entirely below it, and therefore separated from its cavity by the impermeable flooring of the *fascia propria*. The trunk-lymphatics ultimately empty themselves either into one single gland, or else, more commonly, into a series of glands situated on the inner aspect of the ischium, close to the obturator foramen. From these lymphatics ascend behind the pubes, and directly communicate at the level of Poupart's ligament, with the vessels from the thigh. They then ascend in front of the peritonæum and behind the rectus and its sheath, and follow the epigastric vessels upwards. The lymphatics of the uterus, on the other hand, actually pass between the layers of the broad ligament on their way to the lumbar glands, but they pass in the very uppermost part, quite above its cavity.

"Pelvic cellulitis thus begins as lymphangitis, produced by any severe irritation of the vagina or cervix. Then the large lymphatic gland or glands close to the obturator foramen, to which the large lymphatic vessels lead, become involved, and enlarge, and may be detached, on examination, from the vagina. The inflammation may extend to behind Poupart's ligament or even form a hard mass, palpable through the rectus, and following from the groin upwards the course of the epigastric vessels."

In answer to a question of Dr. LYMAN'S, Dr. FIFIELD replied that the peritonæum covered three-fourths of the circumference of the Fallopian tube.

Dr. SINCLAIR, after referring to Dr. Winsor's case of imperforate hymen, once reported to this Society, the operation having been followed by a great abscess, said that his belief was that Dr. Blake's case was one of localized peritonitis.

Dr. BLAKE replied that tumors from localized pelvic peritonitis were recognized, in addition to which one must acknowledge a certain number of pelvic tumors, movable, not connected with the uterus and producing no impression on the vagina. In the case reported by the president there was, he thought, probably an inflammation of the broad ligament.

Dr. CUSHING, of Dorchester, spoke of the treatment of leaving pelvic abscesses to their own course. In a case which occurred under his observation many years ago, the pregnant woman, whose child had been dead a month, had acute febrile symptoms with general tenderness all over the bowels, beginning about forty-eight hours after delivery. The secretion of the milk, following delivery, was very good, and continued cathartics given for quite a number of days in succession brought away hardened feces. The general febrile symptoms abated, and the patient was up and about in two months, but with local tenderness and general nervous symptoms until the end of a year, then the whole affair was discharged through the vagina. Later a second purulent discharge occurred, and the woman finally recovered perfectly. In another case the abscess pointed over the symphysis pubis, and discharged spontaneously; no drainage tube was used, and the patient recovered perfectly in course of time. Dr. Cushing had seen several of these abscesses; they all did well.

Dr. BLAKE stated that he much preferred to elect the point of opening, and cited the case of a patient who died as the result of a spontaneous opening into the abdominal cavity, and several other instances of death in cases where the pus had been left to find its own exit.

Dr. FIFIELD said he had seen them break into all sorts of places and do well. He thought Dr. Blake's case might have been a cyst of the broad ligament. He mentioned the case of a little girl who was supposed to be suffering from retained menses, but in whose case there was coexistent diarrhoea. The rectal discharge proved to be pus, showing abscess as the

real difficulty. The tumor of this abscess was readily felt in the middle line above the pubis, and had been supposed to be the womb swollen with retained discharge, whilst the ostium vaginae had been taken for the mouth of the uterus. In this case the abscess had appeared after the child had spent some time lying on her abdomen on the ice, watching her companions skate. It was probably an abscess occupying the space known as that of Retzius or of Hertaux.

DR. CUSHING, referring to the fact that in an ordinary abscess one gets information from nature as to the point of selection for opening, said he would apply the same natural principles in gynecological practice.

DR. SINCLAIR remarked that the pelvic abscess is not always unilocular; one point may be indicated by nature, yet after the first opening the principal discharge may occur by some entirely different channel.

DR. CUSHING remarked that in Dr. Hosmer's case the opening had to be repeated, or at least it had been necessary to keep in the drainage tube.

DR. BLAKE admitted that cures sometimes occurred after spontaneous openings, but thought nature in these cases rather a blind guide, and remarked that where the opening was controlled the after-treatment was likewise to a great extent controlled.

DR. CUSHING observed that his own experience was probably limited, but he could not recall a case in his practice which did not get well spontaneously, and without leaving a fistulous opening. As to abscess of the breast, he said he was always glad to get a full and free opening, but when he had found the spot which nature indicated there had been generally but little trouble afterwards.

DR. RICHARDSON recalled two cases in which the abscess opened into the abdominal cavity with fatal result.

DR. SINCLAIR thought many years ago, from data then available, that the rate of mortality in pelvic abscess was about four per cent., he now believed it to be much larger.

JANUARY 14, 1882.

#### SUBINVOLUTION OF THE UTERUS.

A paper on this subject was read by DR. SINCLAIR.<sup>1</sup>

DR. BAKER remarked that the disease shows two pretty well-defined stages: first, that of increased vascularity; second, as the disease goes on and the connective tissue becomes disproportionately developed over the natural tissue, a want of vascularity. Thus to the tendency to menorrhagia succeeds a very scanty flow accompanied with very great pain. This latter condition is like that of cirrhosis, dense and firm and creaking under the knife. Then it is that local blood-letting will be of the greatest relief to the pain, and in this respect a leech, applied before the advent of menstruation, will relieve more than scarification. One could do a great deal by treatment to ameliorate the patient's suffering. As to the question of preventive measures, Dr. Baker had found subinvolution much less frequent among the poorer than the better classes. In a person whose nervous force had been sorely taxed, or in a nervous system of feeble force, there was less stimulative power to be aroused, and thus less contracting power of the uterus, hence a greater risk of subinvolution.

DR. LYMAN said that the cases to which Dr. Sin-

clair had referred in his paper were those of arrested involution after labor; but the condition found in chronic metritis was rather of enlargement from congestion and hypertrophy of the connective tissue. In puerperal subinvolution there was pathological evidence that the disease was due to some want of, or interference with, contractile power, the disintegration going on, but its products not being absorbed.

DR. SINCLAIR said he had examined his records of the past ten years and had found a larger number of cases than he had expected. He would not undertake to draw the line between subinvolution and chronic parenchymatous metritis, for he had learned to look at this condition as not metritis at all. He had now and then observed cases similar to those described by Dr. Baker, where the uterine tissue was very hard, and yielded with great difficulty to treatment.

DR. BLAKE was inclined to think with Dr. Baker, that this was a constitutional disease. From extensive practice among the middle classes he had inferred that it was not a common thing to find among them cases of subinvolution. Persons of robust constitution and good general health recovered well without this complication, but among those whose nervous systems were more taxed, the cases were more frequent.

DR. BIXBY asked Dr. Sinclair if the modern ideas of laceration of the cervix had not modified former notions of subinvolution. As a matter of fact, where there had been a deep, single or bilateral laceration the uterus had never come down to its normal size by actual measurement. In a case of bilateral laceration of five years' standing, the labor having been followed by frightful hemorrhage, there was very slow recovery. In a case, also, of laceration with procidentia, the depth of the uterus was five inches. In this instance Dr. Bixby sewed up the lacerations and kept the woman on her back for several weeks. She got well and had no further trouble.

DR. BLAKE remarked that Dr. Bixby had emphasized the most important point in the discussion, namely, that whenever these lacerations have been relieved the uterus has diminished in size.

DR. BOARDMAN said that his experience at the City Hospital, as well as in private practice, had led him to question the accuracy of the prevalent opinions with regard to the connection of cause and effect between lacerations of the cervix and subinvolution of the uterus. He was quite well convinced that the enlargement of the uterus, so frequently found in association with lacerations, is not usually the result of subinvolution, but of later pathological processes, which have their origin in an irritation induced by friction of the everted lips of the cervix against the walls of the vagina. But this friction cannot occur unless the uterus is out of its normal position. If the uterus is not displaced complete involution may, and probably will, ensue after labor; this view is confirmed by the fact that cases are met with constantly where there is a laceration without any enlargement of the uterus, and in these cases the organ always is in good position. On the other hand if a displacement exists before the laceration occurs, then subinvolution most likely will ensue.

DR. BLAKE said that he would consider a laceration extending through one or both sides of the cervix, and attended with eversion, a case for operation. Incisions for dysmenorrhœa, as in artificial openings for chronic cystitis, were never followed by permanent separation.

<sup>1</sup> See page 337 of this number of the JOURNAL.

Dr. BIXBY observed that any one who had had an extended experience in the treatment of uterine disease, would remember how obstinate are these so-called cases of ulceration. The longer he studied the subject of laceration of the cervix, both in its clinical and anatomical aspects, the more was he convinced of the fact that involution failed to take place because the contractile powers of circular or sphincter muscles were destroyed by the solution of continuity. Of this he thought we had abundant proof in the case briefly referred to above.

Dr. LYMAN remarked that he did not remember a case of lacerated cervix in which there was not so-called chronic metritis as the result of local congestion from the everted cervix, nor did he recall an instance in which, *the disease being due to this cause*, the uterus did not become reduced, and generally rapidly, after reparation of the laceration. Most of these cases of laceration may have been, doubtless *were*, followed at first (as indicated by Dr. Boardman) by a fair degree of uterine contraction, the subsequent enlargement being the result of local irritation, the so-called chronic metritis.

Dr. BOARDMAN remarked, in reply to questions which had been asked, that he would state, in the words of the originator of the operation, that a laceration exists when the tear extends beyond the crown of the cervix, and that in many cases where the cervix had been incised the parts had speedily reunited, as we know freshly cut, healthy tissues are prone to do; in others, no malposition of the uterus was present to cause eversion of the lips and friction; and in the remaining cases, where a displacement was present or occurred subsequently, he was confident that a series of events must have occurred similar to that which I have stated are observed as the result of laceration during labor.

Dr. BLAKE averred that it was almost impossible to discover without a post-mortem examination the difference between subinvolution and metritis; they were both the same pathologically. He thought the tear itself an interference with both the contractility and the circulation of the organ.

Dr. LYMAN suggested that it would be better to call the results of laceration evolution, the normal contractions of the uterus being not only arrested after reaching a certain point, but the organ actually enlarging in time under this condition.

Dr. BAKER said that as to the extent to which laceration could occur and disease follow or not, he agreed with Dr. Boardman. If the laceration should be confined to the crown, no trouble would be likely to follow, but if beyond, eversion and uterine disease would result. He did not agree with Dr. Reynolds as to laceration as necessary evidence of pregnancy. As to the effect of incisions, which had been already spoken of, these he regarded an altogether different condition of the uterus. In the large, heavy uterus, found after labor, a tear had the greatest tendency to produce subinvolution, and did not itself tend to heal. The eversion might affect both lips, or oftentimes the anterior alone would be the one to evert. In incisions, such as had been done for dysmenorrhœa, on the other hand, one was dealing with a different uterus, small and healthy, showing the greatest tendency for the incision to heal up, making the healing, in fact, difficult to prevent. Dr. Baker said he had seen an incision carried quite down to the vaginal junction without producing eversion.

Dr. SINCLAIR observed that cases of subinvolution occurred in the absence of laceration, and resulting, it might be, from diminution of nerve force, affections of the heart, dyspepsia, disease of the liver, etc.; and that there were so many cases from various causes that it was often impossible to fix the latter with great accuracy. He thought it marvelous if a true subinvolution had been cured by the simple sewing up of the cervix.

#### A CASE OF PULMONARY EMBOLISM ON THE NINTH DAY AFTER DELIVERY. RECOVERY.<sup>1</sup>

Dr. C. E. STEDMAN read the case.

Dr. FIFIELD remarked that Dr. Fordyce Barker had reported a similar case, with recovery, the syncope having been overcome by holding lighted matches near the apex of the heart, to stir it up. In the convulsions of children, in the critical condition, in which there had been suspension of the respiration with lividity, hot irons from the stove had proved efficacious. A gentleman at a Turkish bath once saw a bather brought from one of the rooms in a horrible condition, apparently dead, and suggested to the attendants to stand the patient on his head to restore the blood to the brain, as is done in syncope, but they, instead, applied boiling hot water to the region of the heart, by means of towels wrung out in it, and the man recovered.

### Recent Literature.

*Epilepsy and other Chronic Convulsive Diseases: their Causes, Symptoms, and Treatment.* By W. R. GOWERS, M. D., F. R. C. P. London: J. & A. Churchill. 1881. xiv. and 309 pages.

A desire to first read this book carefully has led to some delay in noticing it. Dr. Gowers is well known, through his earlier writings, as a careful, painstaking observer, not given to drawing hasty conclusions from a few data. It is a satisfaction to have a careful analysis of a large number of cases of epilepsy, such as is to be found in this volume. Fourteen hundred and fifty cases, treated chiefly at the National Hospital for the Paralyzed and Epileptic, furnish the material from which the book is built up.

Dr. Gowers classifies these cases into purely epileptic, 815 in 1000, and hysteroid attacks, 185 in 1000. By hysteroid he means those cases which Charcot has described as hystero-epilepsy. This is the only attempt to compare the frequency of the two forms of convulsive disorders which has come to our notice.

The book is chiefly a comparison of these many cases, and details his own experience with the disease. Many interesting facts are brought to light. More than one quarter of the patients were under ten years of age when they had their first fit; nearly one half were between ten and twenty; after forty very few began to have the disease. Twelve and a half per cent. commenced during the first three years of life. "In this group no cases of simple infantile convulsions are included, only such as, beginning in infancy, continued as chronic epilepsy." Dr. Gowers does not say at what date the second fit occurred in these cases; in many instances the second attack is long delayed; in such cases it is incorrect to call the early fit epileptic, it is infantile convulsion, and, as a result of the processes causing it, the brain is so af-

<sup>1</sup> See page 339 of this number of the JOURNAL.

fects as to favor or cause the subsequent attacks of epilepsy. Thirty-five per cent. showed evidence of neurotic inheritance.

In speaking of exciting causes the author refers to rickets as being associated with almost all convulsions during dentition, that is, the convulsions depend upon the irritability of the nervous system which accompanies rickets. He refers to the history of late teething, late walking, and in many the crooked limbs, as confirming this opinion. It seems to us that the above defects in development are quite as likely due to the shock which the nervous system sustains at the time of convulsions. When a child has convulsions leading to injury of the brain or caused by such injury, whether paralysis results or not, certainly it is not strange that the child should walk and talk later than normal.

Nearly ten per cent. of the cases were traced to fright as a cause. This is a very large percentage, much larger than we have found to exist: indeed, fright in our experience is more likely to give rise to chorea than to epilepsy. Sunstroke is much less common in England than here, and exposure to the sun is mentioned as cause in only twenty-seven, in six of these the exposure was in the tropics. Scarlet fever leads the acute diseases causing epilepsy in nineteen cases. Syphilis is credited as a cause in only a very few cases.

The chapter on symptoms contains many interesting observations, only a few of which can be noticed. An aura preceded the attack in half the cases, was unilateral in eighty-six cases, began in the arm in forty five of these, in the leg in fifteen, and the face in seventeen cases. He says, "A fit beginning in the face or tongue, if it involves the limbs, takes the arm before the leg, and we find that the arm centres intervene between those for the face and tongue, near the fissure of Sylvius, and those for the leg in the upper part of the hemispheres," and there are other interesting references in explanation of various phenomena. The whole question of the "aura" is considered quite exhaustively, and this is one of the best parts of the book.

He reports one case in which there was an epileptogenic zone at the upper edge of the *left* scapula, the spasms beginning in the right arm. Very few of such cases have been reported. Otto mentions one where snapping a hat elastic caused the attack. Triper mentions such a zone in a case of neuralgia of the face.

In considering the minor attacks Gowers recognizes that consciousness may be retained during the attack, though it is probably modified in some degree. The automatic actions which sometimes seem to replace an attack, and which have been called "masked epilepsy," he considers as post-epileptic phenomena occurring after a minor attack, and thinks that epileptic mania is of this nature.

In regard to the very important subject of mental failure in epileptics he says, "Mental failure is determined less by single conditions than by their combinations, and it is probable that a more potent cause than the attacks themselves consists in a predisposition to suffer under their influence, — a predisposition which is related to the ultimate causes of the disease rather than to its developed characters. Of the latter, early age at commencement, long duration of the disease, and frequency of attack, are more influential than the sex of the sufferer, the existence of heredity, or even the character of the attacks, so far as concerns the mere distinction between major and minor fits."

In speaking of the nature of the lesion in epilepsy

he rejects the theory of disease of the medulla oblongata and hippocampus major and the cerebral anemia theory. He says, in conclusion, "that all the phenomena of the fits of idiopathic epilepsy may be explained by the discharge of gray matter; that the hypothesis of vascular spasm is as unneeded as it is unproved; that there are no facts to warrant us in seeking the seat of the disease elsewhere than in the gray matter in which the discharge commences; that this is in most cases within the cerebral hemispheres, probably often in the cerebral cortex, although possibly in some instances lower down, even in the medulla oblongata; that epilepsy is thus a disease of the gray matter, and has not any uniform seat."

He very properly speaks of *arrest* of treatment and not of cure or recovery. But in giving statistics he does not state how long patients remained under observation after the arrest, hence his tables lose very much of their value; the numbers are also very small, considering how many cases were under observation, — only one hundred and forty-three cases are enumerated, unimproved forty-three, arrest of attacks one hundred.

In treatment bromides are strongly advised. He begins with doses of two or three drachms every second or third morning, and increases the dose to four drachms every fourth morning, and six drachms or an ounce every fifth morning. These large doses should be given after breakfast in a tumbler full of water. The maximum dose should be reached in two or three weeks and repeated three or four times, and the doses then gradually reduced, so that the whole course lasts six or seven weeks. After such a course of treatment the patient remains free from fits for four to six months; but if left without the remedy the fits recur, so the drug should be continued in ordinary doses.

Other drugs, as digitalis, belladonna, opium, zinc, etc., are considered, but the chief reliance is upon the bromides. This notice is already too long, and it is not necessary to dwell further upon particulars. The book is well worth reading. It gives an analysis of Dr. Gowers' experience, and is a careful review of the cases he has seen, rather than an abstract, didactic treatise made up of the observations of others; hence it is alive with useful, valuable observations and suggestions.

*Memoranda of Physiology.* By HENRY ASHEY, M. D. Third Edition, thoroughly revised, with additions and corrections by an American Editor. New York: William Wood & Co. 1882. 16mo. 306 pages.

This little volume, whose outer semblance is rather suggestive of poetical contents, is a quite prosaic *crum* book. It is confessedly published merely to enable students to get through the English medical examination in physiology, and may perhaps help some students in reviewing the subject, and assist others to acquire sufficient fictitious knowledge to pass. It is an abbreviated compilation from Quain and Gray's *Anatomy* and Foster's *Physiology*, but in the process of condensation a not small number of inaccuracies have crept in, which, however, are not important enough to interfere with the employment of the book in cramming for the sake of getting through an examination, but which suffice to render the book little adapted to any higher use. It is perhaps a fortunate modesty which has led the "American Editor," who made "additions and corrections," not to place his name upon the title page.

## Medical and Surgical Journal.

THURSDAY, APRIL 13, 1882.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Mifflin and Company, Boston. Price, 15 cents a number; \$5.00 a year including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

## HOMICIDES BY CHLOROFORM.

THE readers of this JOURNAL know very well the stand heretofore taken in it concerning the administration of chloroform as an anæsthetic: deaths from such administration having long ago been herein characterized as unjustifiable homicides warranting judicial interference. For a long time the English medical periodicals, despite the almost weekly reports in their own columns of deaths directly due to this agent, controverted our arguments and denounced our position. Their conduct in this regard has always appeared inexplicable, for so crushing were the facts that it seemed hardly possible that this could be due, as some averred, to local vanity in an assumed discovery, — a “discovery,” as its advocates were pleased to call it, which after all amounted to nothing more than the substitution of a dangerous agent for one that elsewhere had been previously found to possess the power of safely producing anæsthesia.

At length the *British Medical Journal*,<sup>1</sup> moved apparently by the fearful number of deaths it was obliged to record on its pages, felt constrained to admit that “the reasons why chloroform is considered the best anæsthetic, in face of the numerous fatalities which attend it, and the greater safety of ether, are not apparent on the surface;” and again,<sup>2</sup> to declare that “we think it right to call attention to the advisability of preferring that which is held to be the less dangerous anæsthetic.”

Now, at last, comes the *London Lancet* taking a more decided stand. In a late number just received<sup>3</sup> it forcibly proclaims: “Another and yet another death from chloroform. This is the report which now nearly every week reaches us, suggesting one of the most solemn questions that can occupy the minds of the members of our fraternity. The responsibilities of the profession on this count are without limit. It applied and brought in the agent which causes the deaths; on its recommendation the general public accepted the agent, and by and through its voice declared the anæsthetic beneficent and its introducers the greatest benefactors of the human race. Is this all a delusion, and under the fascination of beneficent discovery has there crept into the world another form of death? This is the inquiry which now stares us in the face, and which must be met.”

Indeed it must be met; well may “the public mind

demand, and rightly demand,” it; for the wonder is that, having stared the profession in the face so long, it was not met and definitively decided long ago. Assuredly we can answer for the *Lancet* that it is all a delusion; that the “general public” was deceived by those it honored, who could not avoid knowing the facts of the case, however much they endeavored to ignore them, and who should have done better. For it is true, in the words of the *Lancet* itself, which a little further on candidly says that “from the very first days when it was itself brought in, chloroform brought in death. Within ten weeks of its discovery as an anæsthetic, and long before it had come into general use, it caused the death of a girl of fifteen years of age in this country. Within another month it caused the death of a woman thirty-five years of age, in Cincinnati; a month later it caused the death of a man in Boston, U. S. Before two other months had passed it caused the death of a woman in Boulogne; and from then until now, a period of thirty-four years, probably not a month has elapsed without one or more deaths from its employment.” Notwithstanding all this, and the facts are far from being over-stated, the *soi-disant* discoverer of the anæsthetic power of chloroform, who was well aware of the terrific lethaliferous character of the agent (he had a fatal case under his own administration), did none the less persistently urge its general use, inducing, as far as he could and not always by most reputable means, “patients themselves to force this remedy on us” physicians; and did not hesitate to secure with unseemly eagerness unmerited honors which a temporary local enthusiasm heaped upon him, not as an experimenter merely with an agent brought to his notice by another, but as the veritable discoverer of anæsthesia itself.<sup>4</sup>

In the course of its remarks the *Lancet* adverts to the question, often asked, it says, by “outside observers” as well as by those in the profession, “why the fatalities occur at all,” and deprecates the usual responses, which it appears to consider shallow apologies. Years ago Richardson gave to this question, we contend, the only possible answer. “Chloroform,” said he, “kills because it does kill.” “If it kills,” wrote Petrequin, “it is because it is in its nature a poison.” Why, we may also pertinently inquire, why does aconitine kill? an agent which, on the adjoining page of the *Lancet*, is called “the most active probably of all the poisonous alkaloids.” Why does aconitine kill? Why? because there is in it the killing power! Knowing thus much about it and no more, or about the deadly power of any other poison, the further question seems pertinent also, — What moral difference is there in the administration of the two drugs “in face of” their well-known properties and results.

After all the vital question is, Why, in the name of common-sense and all that is reputable, is the administration of chloroform as an anæsthetic persisted in, or, rather, why is it even permitted by the medical profession, when it is known to all to be so fatal; and when there is another agent, equally good or better, also known to every one to be so safe; an agent,

<sup>4</sup> See this JOURNAL, March 10, 1870, page 187 et seq.

which, there is still good reason for believing, has never killed any one inhaling it, certainly not unmistakably, outright or instantaneously, as chloroform kills every week? Surely personal following, national prejudice, and a propensity to arrogate for one's country what the Edinburgh Provost called "the greatest of all discoveries in modern times," have each and all had victims enough over the water; and it is time that the profession there should be required, if it does not volunteer, to return to the use of the safer agent, whose "beneficent" powers have little or no serious drawback; although by so doing it be tacitly admitted, as Simpson once said, that "for the great thought, that of producing insensibility, the world is indebted to Morton."

And, moreover, the still further question is appropriate and timely, — Why, if the practice of administering chloroform as an anæsthetic is not frowned upon and prevented by the medical profession itself, should not the courts, "without fear or favor" (the *Lancet's* words), interfere and put a stop to such unjustifiable homicides?

#### SUMMER COURSES IN MEDICAL INSTRUCTION. HOW TO UTILIZE CLINICAL MATERIAL.

THE present tendency of medical instruction seems every year to make the graduating student more and more accomplished in the fine distinctions which can be taught in a laboratory, in the differentiation of one kind of cell from another, or in the nice analysis of some fluid, rather than in the broader and varied forms under which disease presents itself, and in the infinite variety of human nature which it is necessary to consider in properly treating it, and the question arises whether as much is done in the way of clinical work as the circumstances of the case will allow.

No one would wish to curtail the advantages which are now offered, and which should be held at their full value, but do we not have a large amount of clinical material annually passing through our hospitals which might be used to better advantage than at present, especially in summer?

There is probably no city of its size which is more bountifully supplied with hospitals and dispensaries than Boston, and the men who carry on the work in them are, as a rule, well prepared both by home and foreign study for their posts.

It occurred to some of them, two years ago, to use the material which passed through their hands for the purpose of instruction, and to give the students, in the summer recess, a chance to see more of actual cases than they could while occupied with the routine of winter lectures.

The aim, as expressed in their announcement, was "to bring within the reach of students the clinical material which comes to the hospitals and dispensaries during the summer months, and to give an opportunity for the formation of numerous small classes under separate instructors."

With this object in view fifteen courses were pre-

pared, most of them being given at six of the hospitals and dispensaries of the city.

The number of students in each class was limited, the largest number being seven, and the average four, the idea being rather to give the student a chance to see and examine the cases for himself, under competent direction, than to afford the instructor an opportunity to display his erudition.

In a few details the methods were new, but in general the courses resembled those of the Vienna hospitals, as given by the privat-docenten, and lasted about six weeks.

The course in obstetrics has been already mentioned in this JOURNAL,<sup>1</sup> each student attending on the average six cases.

In materia medica the plan was introduced, in addition to the ordinary methods, of providing a small laboratory in which the students were required to compound the drugs previously written for, and thus acquire a practical knowledge of the preparation as well as of the therapeutic value of their prescriptions.

Beginning with a few students the first year, the plan has proved a decided success, and the increase last year was so great that a number were refused admission, including some graduates from schools at a distance, on account of the classes being filled.

So long as the idea is kept in view of giving the students an opportunity to see a large number of cases, and so long as the instructors remain, as at present, men who have had the advantage of careful training in foreign schools, as well as at home, the plan bids fair to serve as a very useful addition to the medical opportunities of Boston.

#### MEDICAL NOTES.

— M. Herveux has sent to the Paris Academy of Medicine an interesting report of a new stock of cow-pox, furnished by a heifer sent from Bordeaux. This heifer had, in the vicinity of the teats, about thirty pustules, which, on the fourth and fifth days of their development, showed the characteristics of true vaccine. The matter obtained from these pustules, either by puncture with the lancet or by expression, and inoculated either into heifers or children, produced a crop of pustules entirely identical with normal vaccine. With a few exceptions only the inoculations have produced as many positive results as there have been children vaccinated, and very nearly as many as there were punctures. The transmission of the vaccine from the Bordeaux heifer to those bought for the purpose by the Paris authorities was completely successful, as they yielded as many pustules as there were incisions made. The Paris animal vaccine service has, therefore, been able to substitute fresh cow-pox from the Gironde for their official stock, and this is held to be the more satisfactory as this particular animal vaccine is considered to be of a first-rate quality. — *British Medical Journal*.

— There are established at Paris, along the banks

<sup>1</sup> Page 99, vol. cxi.

of the Seine and Saint Martin's Canal, eight Humane Society houses (*pavillons de secours*). A store of blankets, mattresses, and every appliance necessary to restore life to the drowning is kept at every house. The number of apparatus intended to succor the drowned, deposited at the different police stations in Paris and its environs, including those of the *pavillons de secours*, amount to 267, with 210 stretchers at the prefecture of police. There are besides this ample provision tents, which are requisitioned by the *service de secours* on the days of public *fêtes*, and also for reviews. They are pitched where the crowd is the most dense, and are furnished with all the appliances of an ambulance; a medical man is attached to each of these movable ambulances during the duration of the *fêtes*. From 1805 to 1877, 11,500 sick and injured persons were relieved. Since 1875, 88 out of 196 apparently drowned persons have been restored to life.

—The prophylaxis of small-pox by vaccination and by revaccination is strictly attended to in the English navy, in which the highest danger of infection is in foreign ports, where vaccination is not enforced and revaccination is but little attended to, especially in China and Japan. In 1880, when the total force was 44,700 men, there occurred, in all parts of the world, only six cases, of which the Cape of Good Hope and East Indian stations presented each two, cases, and the China and Pacific stations one each. At the Cape the infected men were both blacks, of whom one had not been vaccinated, and the other was said to have had previously a mild attack of small-pox; of the two in the East Indies, both bore marks of vaccination without revaccination; on the Pacific station, the case ran a modified course, most probably from revaccination; in China, the sufferer had been revaccinated unsuccessfully nine years before.

## NEW YORK.

—The following statistics for the first quarter of 1882, as compared with the same period of last year, have just been reported to the Board of Health by Dr. John T. Nagle, registrar of vital statistics:—

| 1881          | Deaths. | Births. | Marriages. | Stillbirths. |
|---------------|---------|---------|------------|--------------|
| January.....  | 3188    | 2587    | 700        | 212          |
| February..... | 2826    | 2659    | 679        | 191          |
| March.....    | 3141    | 2885    | 828        | 194          |
| Total.....    | 9155    | 6832    | 2228       | 594          |
| 1882          |         |         |            |              |
| January.....  | 3498    | 2278    | 925        | 200          |
| February..... | 3208    | 2002    | 946        | 218          |
| March.....    | 3481    | 2486    | 818        | 199          |
| Total.....    | 10,277  | 6866    | 2689       | 617          |

Of the deaths in the first quarter of the present year, 15 were due to typhus fever, 174 to small-pox, 1146 to scarlet fever, 562 to diphtheria, 403 to measles, 276 to croup, 147 to whooping-cough, and 67 to cerebro-spinal meningitis.

—A stated meeting of the Medical Society of the County of New York was held on the 27th of March,

when, on recommendation of the Committee on Hygiene, endorsed by that of the Comitia Minora, a series of resolutions were adopted to the effect: (1) that it was the imperative duty of the proper authorities to set apart from the lands belonging to the city an appropriate place for the erection of a hospital or hospitals for persons sick with scarlet fever, measles, and diphtheria; (2) that the Society should memorialize the legislature to direct the commissioners of the sinking fund of the city to transfer to the care of the Board of Health, with the approval of the mayor, suitable lands for this purpose on the East River front; (3) that the proper authorities should appropriate sufficient funds for the erection and maintenance of such hospital or hospitals; and (4) that the president of the Society, Dr. A. Jacobi (who originally suggested the proposition), and the chairman of the Committee on Hygiene should be appointed a committee to urge upon the authorities named the speedy execution of this undertaking. At present no hospitals exist upon Manhattan Island proper at which cases of the above diseases are received for treatment, and when such patients cannot be suitably cared for in their own homes it is necessary to expose them to the danger of transportation to Blackwell's Island. In a short time, also, they will have to be carried to North Brothers Island (instead of Blackwell's Island), and this is a much greater distance. The paper of the evening was by Dr. Charles F. Stillman, on Obliquity of the Pelvis, or Sacro-Lumbar Curvature and its Treatment.

—A number of prominent medical men were recently invited to the Ashland House to make an examination of Herr Haag, the "India-rubber man," who was lately at the Westminster Aquarium, and is now on exhibition in this city. It is a case of dermatolysis or loosening of the skin, and almost unique. Haag was born in Erlangen, Bavaria, and he has spent a considerable time in Vienna, where the remarkable elasticity and mobility of the skin attracted much interest among the dermatologists. He is about thirty-two years of age, and has several children, none of whom inherit the father's peculiar cuticle. On this occasion he first took the integument of his chest in both hands, and having drawn it upwards easily put it in his mouth. The skin of his arms and legs was then stretched out until he looked like a bat or flying-squirrel, and he was also able to draw out that of his nose and chin to a most extraordinary extent. The skin upon his ears, hands, and feet also exhibited the same elastic quality. When he was in Vienna a portion of integument about four inches in length was removed from the right arm, and it was found that there was a lack of subcutaneous fat and cellular tissue, which permitted the skin to move very freely over the muscles. Since his appearance at the Ashland House Herr Haag has been presented to the students of the University Medical School and the College of Physicians and Surgeons by Professors Piffard and Fox, respectively.

—Mr. Moses Taylor, of this city, for many years a director of the Delaware, Lackawanna, and Western

Railroad Company, has delivered in trust to Samuel Sloan, president of the company, and Edwin F. Hatfield, president of the Lackawanna Coal and Iron Company, \$250,000 par value of first mortgage bonds of the Delaware, Lackawanna, and Western Company, to be used as a fund for the erection and maintenance of a hospital at Scranton, Pa., for the disabled and sick employees of the two companies. The bonds, with accrued interest, are worth \$270,000 in the market, and the cost of the building will not exceed \$70,000, thus leaving at least \$200,000 for the permanent endowment. The hospital will probably be built on a site tendered by the Coal and Iron Company, and it is expected that articles of association, providing for a board of trustees, will be adopted under the general corporation laws of Pennsylvania. Other patients than employees will probably be received in the hospital, but the terms of their admission have not yet been decided upon.

—At the fifth social meeting of the Yale Alumni Association this season, recently held at Delmonico's, Mr. James T. Gardner, of the class of 1868, read a paper on How to Escape Sewer Poison.

#### WASHINGTON.

*The Garfield Memorial Hospital.* The bill for the incorporation of this hospital came up before the United States House of Representatives, and, after considerable debate, was so disposed of as to probably never again be brought before that body, at least in its present shape. One reason for asking for incorporation by Congress was that the laws of the District do not issue an act for this purpose for a longer period than twenty years, and it was desirable to have an act which should be perpetual. This was met by the recommitting of the bill to the proper committee, with instructions to report amendments to the general law in relation to the formation of corporations in the District of Columbia by extending the time for the duration of such corporations, and otherwise for the establishment of hospitals and other charitable institutions.

Another reason was to enable the incorporators to merge into their proposed hospital the property and funds of the Soldiers and Sailors Orphan Home, representing some \$30,000 to \$50,000, now no longer of use for the purpose for which it has accumulated, because the orphans of the late war have disappeared by the influence of time, but not available until Congress shall sanction its further disposal. All of those interested in the disposal of this fund, except Congress, are desirous that the hospital shall so utilize it. Congress, however, by its action evidently agrees with the views expressed by Mr. Cobb, that there is a very grave question as to whether the board of trustees of this fund of the Soldiers and Sailors Orphan Home can so dispose of it, it having been in great part devised by one person, and the object of the bequest having ceased it should revert to the testator or his heirs perhaps, if there are any.

These were the only valid reasons brought out in the discussion as to why the bill as presented should

not be passed, and both could readily have been put into such a shape as to insure the passage of the bill, were it not for the strong hostile spirit shown, evidently stimulated by other hospital interests; there was a yearly appropriation of \$15,000 to bid for, now used for the support of hospitals in the District, which from its purposes would certainly sooner or later find its way into the projected hospital as a broader, more liberal, and more satisfactory institution than any here at present.

Some of the objections were certainly very forcible. One was a well-timed comment on the use of Garfield's name to better foster such enterprises; there is no doubt it was used mainly to foster the enterprise, and so long as not seen through would have been a commendable act; but Congress did see through it, and Mr. Butterworth very properly so condemned it. Only it is to be hoped that all other enterprises with the name of Garfield as an invocation, and which are not so necessary and praiseworthy, will be similarly treated by Congress.

Another objection was the possible calling for appropriations in the future. This objection was based upon experience and sound reasoning. Mr. Wilson offered an amendment looking to this objection, which is worthy of standing on record, to be taken up from time to time and applied as exigencies arise. It reads: Provided, That if said corporation shall at any time hereafter apply for an appropriation of money for its aid, such appropriation shall operate as a repeal of this act.

After all that has been said and done, there is a great want for such a hospital in this city, and it should receive in every way the proper support from Congress, but failing in that support there is no reason why it should not be attempted, as independent of that body. Once a success, it will be all the more useful and all the more satisfactory for being independent of legislation. Money has come in as donations in considerable amount; the city is no longer simply a home for office holders and government contractors, but intelligent and wealthy property holders are settling in our midst, and every year will see more and more of that class of persons among us who have been accustomed at home to make it their duty to assist in supporting charitable institutions.

*Scientific Lectures.* There is no better evidence that Washington has become a city than the attendance upon the course of scientific lectures now being given at the National Museum. An old resident can look around and say: Who are all these well-dressed people, they appear to be ladies and gentlemen, yet I know very few of them; I do not see them at the receptions or parties? And he may well wonder, for it is only a few years since he knew in that way everybody in town who was worth knowing. These lectures are given every Saturday at 3.30 p. m., are free, and are by selected members of the Anthropological and Biological Societies; they embrace a wide range of subjects, and, besides being in a popular framework, are worthy of permanent preservation for reference; they are accordingly being printed in pamphlet form, as

they appear. Dr. Robert Fletcher is soon (April 15th) to deliver one on the subject of Paul Broca and the French School of Anthropology, and Dr. Swan M. Burnett (April 29th) on How We See. On the day of the last lecture, by actual count at the door, fourteen hundred persons passed into the National Museum; the trouble now is that there is not room for those who wish to attend these lectures, and their success has led to the presentation of a bill before Congress which shall provide for the selection by the proper persons of suitable lecturers and subjects for a regular free course of scientific lectures, — the necessary expenses to be defrayed by an appropriation.

The interior of the National Museum building is still chaotic, but the medical visitor who goes there properly introduced can see much that is of professional interest, although not yet open for general inspection. The collection of *materia medica* is of especial interest, and the Chinese have a case which, although taken from the Centennial Exhibition, is perhaps not well remembered. They have taken panels of different woods, encased them in a framework of the bark, and given cross cuts of the same as a finish to the four corners of the frame; upon the panel of each is delicately painted the leaf, the flower, and the seed, — all pertaining to the same specimen.

### Miscellany.

#### CREED OF AN OLD M. M. S. S.

MR. EDITOR, — In a very cordial letter received a day or two ago from a valued professional friend occurred an incidental remark as to what "we both admit, I suppose," in regard to certain modern assumptions. This remark induced a reply to qualify his supposition; and has since led to the idea that, while the current "scare" about small-pox is passing away, or has in a measure subsided, the publication of an ancient practitioner's creed, containing nothing new perhaps to coevals, may not be inappropriate or wholly useless, though the doctrines implied in it seem to have been somewhat overlooked or disregarded in recent practice.

#### CREDO

That the degree of susceptibility to a given disease depends upon and is a part of the inborn bodily idiosyncrasy of the individual, and cannot be known or estimated except by a thoroughly adequate exposure to the disease in question.

That this susceptibility to a given disease is not the same in any two persons; and that any two diseases will not affect the same person with equal severity.

That acute diseases, especially those of a contagious or infectious nature, are seldom repeated in the same person; in popular language, are seldom taken twice.

That the degree of protection against a second invasion of a disease is not in proportion to the severity, either during the progress or in the sequelæ, of the first attack. Nor is the damage, general or local, done by a disease a trustworthy guide in this respect. Thus, in small-pox or vaccine disease a scar is good for nothing as a measure of immunity, a person having large scars being as likely as any other to have an after-attack or second taking; these scars, not essential to the

disease, indicating, if they indicate anything, a severe local result of a previous affection, and, if large or many, in consequence of mishap or of great natural local susceptibility.

That vaccination, once thought infallible, be it ever so thorough or often repeated, will not protect *every one* against a subsequent attack of small-pox; a fact believed to be pretty generally admitted nowadays.

That small-pox itself will not prevent in all instances a second attack of the same disease; witness, almost every practitioner's observations, and cases reported by Drs. Green and Webb in a former epidemic.

That susceptibility, not time or change, organic or functional, from infancy to adult age, determines a second or after-attack; witness, oft occurring instances and a case reported by Drs. Green and Webb, where under their own observation throughout, a child less than a year old had small-pox twice; the second attack, one month after the first, being fatal.

That in small-pox and vaccination what is once done is done for all time; revaccination, if resorted to, being useful merely as a *test* to determine whether the first vaccination fully exhausted the susceptibility (to itself, not to other disease), and being needed, if needed at all, as much within a few days as at any time afterwards, or no more at one time than another; witness, many examples (the writer's case among others). Ordinarily, therefore, after such a test, revaccination should not be repeated, as, to say nothing of "misadventures," it may cause severe and possibly characteristic disturbance without adding to the immunity from small-pox. Even after small-pox itself, and in those insusceptible to it, similar results will sometimes occur upon vaccination.

It has been surmised, probably from imperfect knowledge, that were custom to compel every physician to revaccinate his own patients whenever requested, *without extra charge*, there would be much less said about the necessity of third, fourth, and more vaccinations.

That the true test of complete immunity from small-pox through vaccination, and the only one absolutely trustworthy, is repeated and thorough exposure to small-pox itself, that is, by inoculation or by close contact with it. Many years ago Dr. Gregory thought so, and inoculated his own child with variolous matter after vaccination.

That contagion and infection have a more limited range than generally accredited to them; and that it would be well always to receive *cum LIBRIS suis* the varied and sensational stories of disease being communicated through old garments, rags, letters, etc., including also the "traditional trunk." In an account of "shoddy" manufacture in England it was stated, in 1867, that "old woollen rags . . . come to Yorkshire from districts where plague, fever, small-pox, and loathsome skin diseases prevail; they are sorted by human fingers when the bales are opened before being placed in machines which tear up and clean the fibre for manufacture; but the Pollution of Rivers Commission [a Government Commission, — good authority certainly] mention that fifty years' experience has proved that these rags are not in any degree dangerous to the health of those who work among them, although in many of the countries where they are collected they are believed to be peculiarly plague-bearing materials. . . . The dirt, dust, and fine particles blown

out by the machine are collected and sold for manure at from ten to twenty shillings per ton. . . . From seventy to eighty millions of pounds' weight of shoddy were used in a year."

Two years ago the writer was told by a gentleman that his family, father and sons, had been owners and managers of paper mills for more than a hundred years: that in their business of paper-making they had consumed hundreds of thousands of tons of rags, these rags coming, often in most filthy condition, from hospitals, lazarettos, dead-houses, and the like, from Russia, and all European ports, from Turkey, Smyrna, and the East, yet in all their experience they had never known a case of disease to be contracted from these rags by persons working in them. Frequently over a hundred women, as well as men, had been employed at a time in picking over and cleaning these rags by hand. Similar testimony comes from other mills, which have had like experience, though the work is described to be often loathsome *usque ad nauseam*.

That, while cleanliness may be next to godliness, neither of these attainments will effectively bar out disease, which at times seems to have an especial taking for the pure and upright; and that, while isolation is sometimes absolutely imperative, segregation of the sick is always desirable, as much for themselves as for the well, who should never be allowed free access to the sick, when conveniently prevented, except for some appropriate service.

#### ETIAMQUE CREDO, TREMISCENS.

That in the spread of diseases less is due to other causes than to epidemic influences, of the coming and going of which not so much is known as of the wind which bloweth where it listeth: and that it would seem more becoming, as well as more truly scientific, so long as an actual preventive or a real disinfectant is yet to be discovered, to use less laxity of speech in claiming control over epidemics or discovery of their causes; to talk less positively of "stamping out" disease; and to be a little more cautious in laying down rules and orders, many of which as promulgated are too impracticable, not to say absurd, to gain the active co-operation of experienced persons, out of as well as in the medical profession, and which, to that extent, are worse than useless, nay, are seriously detrimental to the peace and safety of a community. MORTOCULUS.

#### "UNUSUAL OR ACCIDENTAL RESULTS OF VACCINATION."

BOSTON, March 27, 1882.

MR. EDITOR,—Having noticed Dr. Alfred H. Holt's article on Unusual or Accidental Results of Vaccination in the JOURNAL of March 23d, I should like to call your notice to three of my dispensary cases which resemble Dr. Holt's in almost every detail. The first two cases were brothers, aged ten and twelve years, who had been vaccinated by the city authorities ten days previous to my being called to see them. At least seven eighths of the elder boy's body was covered with an eruption resembling exactly that described by Dr. Holt, although, as I did not examine it with a lens, I cannot say what the microscopic appearances were. The mother said the eruption had appeared on this boy the previous day, with no accompanying symptoms whatever. An eruption had begun to break out on the surface of the younger boy early that morning, and

I noticed several papules on the face, which made me think of varioloid, but as there had been no prodromic symptoms whatever I doubted it, and upon visiting them the next day the eruption on the younger boy resembled exactly that of his brother on the previous day, while the eruption on the latter was beginning to fade. In three or four days both eruptions had entirely disappeared, having gradually assumed the brownish hue mentioned by Dr. Holt. In both cases the vaccination pustules were well marked, with a good deal of swelling and redness about them. Neither of the boys had been exposed to small-pox to my knowledge, and the cases differ from those of Dr. Holt in that there was not the slightest feeling of malaise either before or during the appearance of the eruption.

The third case was that of a boy, aged seven, who was covered with exactly the same kind of eruption as the others, it having appeared about nine days after vaccination. In this case there were also well marked vaccination pustules, and there was marked constitutional disturbance, fever, headache, and malaise. There was no history of exposure to small-pox, but the boy had always been rather delicate. The result was the same as in the other cases. I have been able to find no description of a similar eruption following vaccination in any book on the subject. I think there are other physicians in this city who have had similar cases, and it would be well to report them.

Very truly yours,

VINCENT Y. BOWDITCH.

#### ICE-WATER AND AMERICAN DYSPEPSIA.

MR. EDITOR,—I am somewhat surprised at the query of your correspondent S., and at your own skepticism in regard to the injurious effects of excessive ice-water. I have always looked upon the dictum of the State Board of Health as gospel in matters connected with medicine. Let me quote a few sentences from a paper by its first secretary, Dr. George Derby, on the Food of the People of Massachusetts: "Dyspepsia is too common a complaint among our people to warrant the overlooking things that, to other people, may seem trivial and unimportant." "In our manufacturing of all kinds, water (very often iced) is placed within easy reach of every person, and the effect of this constant invitation is seen in the drinking of what physicians must regard as unreasonable amounts; the food is thereby diluted, and the stomach is oftentimes chilled below the temperature of the blood, and by repeated draughts may be kept in this condition. The process of digestion is in this way seriously interfered with." Many similar quotations might be made from the same article to show the opinion of a man who has done much to mould public opinion in this vicinity on the subject of dyspepsia. Has a strictly American education made me too credulous in regard to our local authorities? AMERICUS.

#### ETHER VERSUS CHLOROFORM.

WE feel sure that the gradual introduction of ether into general use in Great Britain is a source of great interest to our readers, and that they will welcome the following paper on the subject by Mr. T. Pridgin

Teale, Surgeon to the General Infirmary at Leeds, which we reproduce from the *British Medical Journal* of March 11, 1882:—

It is confessedly difficult, perhaps even impossible, to settle by statistics the question of the relative danger of these two anaesthetics; chiefly for the reason that, whilst we know pretty nearly how many deaths from each agent occur during the year, we have not the means of ascertaining the relative proportions of the cases in which each anaesthetic has been used.

Such being the case, it may be worth while to record the opinions of those who, having for a great number of years had experience of chloroform, have also for many years (in my own case, more than six years) almost abandoned it in favor of ether. I wish, therefore, to tender my conclusions for what they are worth, based, as they are, upon what I have seen in the practice of my colleagues and myself at the Leeds Infirmary, and upon experience of anaesthetics in my private practice. My conclusions are as follows:—

(1.) Ether, *properly administered*, is a much safer anaesthetic than chloroform. So much safer do I believe it to be, that I counsel every surgeon whom I can influence in the matter to study the method of its right administration, and to let ether take the place of chloroform. The exceptions I make in favor of chloroform, are: in infants, in patients subject to asthma or chronic bronchitis, and also, perhaps, in cases of abdominal obstruction, with difficult breathing, in which an operation has to be performed.

(2.) When many operations have to be done in rapid succession, to use ether is a great economy of time. A good "etherist" can get most patients under its influence in from one and a half to two minutes, whereas, in my experience, chloroform must be given from six to fifteen minutes before an operation can be commenced. I am aware that chloroformists trained in Edinburgh usually administer chloroform more rapidly than those trained in English hospitals.

(3.) A patient under the influence of ether is far more passive, and therefore in a more convenient condition for operation, than one under chloroform. As soon as the effect of chloroform is passing off, the patient becomes, as a rule, and often very suddenly, very sensitive to pain; whereas, in the case of ether, especially if the patient have been kept for some time under its influence, the return of sensibility to pain is very slow. In fact, a patient may become so far conscious as to converse with the surgeon whilst stitches are being placed in the wound, and at the same time be entirely unconscious of pain. This was not my experience of chloroform.

(4.) When ether is administered without food on the stomach troublesome sickness is very rare.

(5.) In using ether, the *safety and comfort of the patient, the rapidity of the anaesthesia, and the convenience of the surgeon* in operating depend very directly upon the *method of administration* employed, and the *manner* in which the administrator does his work.

(6.) There are good methods of administration of ether and bad methods, and there are good and bad "etherists." The varying opinions of the value of ether which prevail in the profession probably depend very directly upon the varying methods and manners of administration.

(7.) It is a bad method to give ether "on a towel," as first taught us by Dr. Joy Jeffreys, to whom Eng-

land is deeply indebted for his successful crusade in favor of ether. This involves a great waste of ether, ten to twenty ounces being required. The patient's lungs are chilled, and bronchial râles, struggling, and maniacal excitement not infrequently result. I, along with my colleagues, commenced ether under this system as a duty, and by no means an agreeable one, and held on doubtfully when I suspected that some patients probably died from the effects of the chilling of the lungs.

(8.) It is a bad method to give ether with the American basket-work frame, which, though not much better than the towel, served a good purpose as a step to better things.

(9.) The good methods are those in which the patient breathes over ether into an India-rubber bag, a method, I believe, introduced into practice by Dr. Ormsby of Dublin, and carried to further perfection by Mr. Clover. In this method, the patient breathes the same air over and over again for six or eight times, thereby economizing the heat of the air-passages, economizing ether, and enhancing the effect of the ether by partial asphyxia. My experience of the use of Clover's smaller inhaler, under good management, is this: *a.* A patient can generally be ready for operation in a minute and a half, sometimes in less than a minute; *b.* There is rarely any struggling; *c.* Noisy excitement hardly ever occurs—perhaps, in my private practice, once in a hundred times; *d.* Râles in the trachea are but seldom heard; *e.* Instead of six or eight ounces of ether being used in a short operation, and sixteen to twenty in one lasting an hour or an hour and a half, half an ounce or less suffices for a short operation (such as "splinter-stretching" or "iridectomy"), and two to three ounces for an operation of an hour's duration, such as colotomy or excision of a joint.

(10.) The administration of ether by inferior methods is too common, and was until recently prevalent in some of our larger hospitals.

(11.) Even with Ormsby's or Clover's inhalers, there is an infinite variety of skill in different etherists.

(12.) In order to become a good etherist, the administrator must *study how* to give ether, must *watch* the patient *attentively* whilst giving it, and during the earlier inhalations must very carefully and *studiously* adjust the anaesthetic to the sensations of the patient.

(13.) A careful, attentive student, with tact, and not hard and unfeeling, can easily and in a short time be taught to give ether properly.

Since the adoption of Clover's inhaler, I have had singular freedom from anxiety about my anaesthetics—far greater freedom than in the previous period, when I had to depend upon chloroform.

Finally, I would say that this favorable opinion of ether is based upon my experience of its use by a series of very able administrators—some in the Leeds Infirmary, others whilst acting as my private clinical assistants. Speaking as a looker-on, rather than as an administrator, I should say that the chief points in the right administration of ether are: first, to overcome the nervous dread of the patient by applying the mouth-piece only; then to turn on the ether gently, until the glottis becomes tolerant and the patient is slightly unconscious; lastly, to complete the anaesthesia rapidly. In advising beginners, I compare the regulation of the quantity of ether to the "curve of harmonic progression."

A COMPARATIVE VIEW<sup>1</sup>

OF THE

## NATURAL SMALL-POX, INOCULATED SMALL-POX, and VACCINATION,

IN THEIR EFFECTS ON INDIVIDUALS AND SOCIETY.

## NAT. SMALL-POX.

For 12 centuries this disorder has been known to continue its ravages, destroying every year an immense proportion of the population of the world.

It is in some few instances mild — but for the most part violent, painful, loathsome — dangerous to life, and always

## CONTAGIOUS.

One case in three dangerous, ONE IN SIX DIES.

At least half of mankind have it, consequently one in twelve of the human race perish by this disease. In London 300 die annually : 40,000 in G. Britain and Ireland.

The eruptions are numerous — painful, and disgusting. Confinement, loss of time and expence are certain, and more or less considerable. Precautions are for the most part unavailing. — Medical treatment necessary, both during the disease and afterwards. It occasions pits, scars, fevers, &c. disfiguring the skin, particularly the face. The subsequent diseases are scrophula in its worst forms; diseases of the skin, glands, joints, &c. and lots of lentic, fight, or hearing, frequently follow.

It is attempting to cross a large and rapid stream by swimming, when one in six perishes.

## INOCULATED SMALL-POX.

For the most part mild, but sometimes violent, painful, loathsome, and dangerous to life, always

## CONTAGIOUS,

and therefore gives rise to the Natural Small-pox — and has actually, by spreading the disease, increased the general mortality 17 in every 1000.

One in forty has a dangerous disease, ONE IN THREE HUNDRED DIES. — And in London one in 100.

Eruptions are sometimes very considerable, confinement, loss of time and expence certain, and more or less considerable — preparation by diet, and medicine necessary, extremes of heat and cold dangerous, — during ill health, teething and pregnancy to be avoided — medical treatment usually necessary. When the disease is severe deformity probable, and tubercular disorders as in the Natural Small-Pox.

It is plying the river in a boat subject to accidents, where one in 300 perishes, and one in 40 suffer partially.

## VACCINATION.

Is an infallible preventive of the Small-Pox ; — always mild, free from pain or danger, NEVER FATAL, NOR CONTAGIOUS.

No eruption but where VACCINATED. No confinement — loss of time, or expence necessary. — No precaution ; — no medicine required, no consequent deformity. No SUBSEQUENT DISEASE.

It is plying over a safe bridge.

the fatal consequences of the small-pox, think it a duty thus publicly to declare our opinion that inoculation for the Cow-Pock, is a certain preventive of the small-pox ; that it is attended with no danger, may be practiced at all ages and seasons of the year, and we do therefore recommend it to general use.

JAMES LLOYD, { Consulting Physicians.

JOHN FLEET, junr. {  
SAML. HUNT, junr. { Attending Physicians.  
JAMES JACKSON, }

## BOSTON DISPENSARY.

AT a meeting of the Managers, June 10, 1803. — The Attending and Consulting Physicians of this institution having informed the Managers, that they have found Inoculation for the COW-POX mild, unattended with danger, and a full security against the Small-Pox — and the Managers desirous that the superior advantages of the Cow-Pox may be fully experienced by the objects of this charity and all others —

Resolved — That we do entirely accord with the sentiments of the Physicians, and earnestly recommend to the poor of the town, to embrace the means now offered of preserving themselves and families from a dangerous and loathsome disease, by the newly discovered and happy mode of Inoculation for the Cow-Pox, which will be performed by the Physicians of the Dispensary — recommendations to whom may be obtained from any of the Contributors to said Institution.

Published by order of the Board of Managers,

S. PARKER, Chairman.

N. B. A Certificate similar to the above has been given to the Managers of the Philadelphia Dispensary, signed by fifty physicians.

Boston, June 25, 1803.

## TYPHOID AND MALARIAL FEVERS.

THE Connecticut State Board of Health's report for January states that the renewed frequency of typhoid fever and the prevalence of malarial fevers side by side is shown by the returns from Hartford, New Haven, and Waterbury, as also in other parts of the State, usually where malarial diseases have prevailed for some years, and the type is changing back to continued fevers. Typho-malarial fever is also reported from Thomaston, or, perhaps, congestive fever rather, in one or two cases causing death after a very brief illness. The milder forms of malarial fever have previous to this been the only existing types. As is usually the case, the severer and more fatal forms come after the others have existed some years. Indeed, there have been but few cases comparatively of any form of malarial diseases about this region. Malarial fevers are also reported from Willington as a recent invasion, and one or two towns in Windham County must, apparently, soon be added to the malarial territory. In Plainville the latent or masked variety is reported as most frequently met, and this is also true of many places where this type has been long prevalent. The frequency is stated to be decreasing in Suffield, but an unusual prevalence of jaundice, both in children and adults, is reported, probably produced by the malarial influences. From South Manchester, Bloomfield, Berlin, and Granby they are reported as being fully as prevalent as last month. The unusually mild winter has been a predisposing cause of malaria, and if any inference can be drawn in so capricious a disease it would seem that this year is to be a favorable year for the increase and spread of malaria. The type is stated to be milder in Oxford while the frequency is unchanged. The principal diseases reported from Unionville are bilious, remittent, and gastric fevers, and but little sickness except of this nature.

— Condensed mare's milk from the Russian steppe is soon to be added to the numerous infant foods.

<sup>1</sup> Parents and others are earnestly requested to attend scrupulously to the above Comparison and to the following Certificate and Recommendation :—

We the consulting and attending physicians of the Boston Dispensary, having carefully considered the nature and effects of the newly discovered means of preventing by Vaccination,

<sup>1</sup> Columbian Centinel and Massachusetts Federalist, July, 1803.

## REPORTED MORTALITY FOR THE WEEK ENDING APRIL 1, 1882.

Deaths reported 3056 (no reports from New Orleans and Cleveland); 1215 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 656, consumption 426, lung diseases 466, diphtheria and croup 185, scarlet fever 136, small-pox 82, measles 63, typhoid fever 40, diarrheal diseases 37, whooping-cough 36, cerebro-spinal meningitis 27, erysipelas 18, puerperal fever 15, malarial fevers 13, typhus fever three, intermittent fever one. From *measles*, New York 44, Brooklyn seven, Chicago six, Philadelphia and Buffalo two each, Baltimore and Pittsburgh one each. From *typhoid fever*, Philadelphia 17, Chicago five, St. Louis four, New York and Boston three each, Buffalo and New Haven two each, Brooklyn, District of Columbia, Providence, and Lowell one each. From *diarrheal diseases*, New York 15, St. Louis five, Baltimore three, Chicago, Cincinnati, Buffalo, Charleston, and Somerville two each, Brooklyn, Pittsburgh, Lowell, and Haverhill, one each. From *whooping-cough*, New York 19, Brooklyn, Chicago, and Boston three each, Philadelphia and Salem two each, Pittsburgh, Buffalo, Nashville, and New Bedford one each. From *cerebro-spinal meningitis*, New York seven, Philadelphia five, Chicago four, Cincinnati and Buffalo two each, District of Columbia, Fall River, Springfield, Somerville, Newton, Brooklyn, and Woburn one each. From *erysipelas*, New York five, Brooklyn four, Cincinnati three, Baltimore two, Boston, St. Louis, Buffalo, and Fitchburg one each. From *puerperal fever*, St. Louis four, New York, Chicago, Boston, and Milwaukee two each, Brooklyn, Cincinnati, and Pittsburgh one each. From *malarial fevers*, New York seven, Chicago three, St. Louis two, and New Haven one. From *typhus fever*, New York three. From *intermittent fever*, Baltimore one.

One hundred and fifty-one cases of small-pox were reported in Cincinnati, Pittsburgh 30, St. Louis nine, Brooklyn five, Baltimore four, Boston three, Buffalo and Milwaukee each one; diphtheria 18 cases, scarlet fever 10, typhoid fever five, in Boston; scarlet fever 15, and diphtheria four, in Milwaukee.

In 35 cities and towns of Massachusetts, with a population of 961,395 (population of the State 1,783,086), the total death rate for the week was 21.80 against 21.50 and 19.27 for the previous two weeks.

For the week ending March 11th, in 173 German cities and towns, with an estimated population of 8,526,789, the death-rate was 28. Deaths reported 4597: under five 2213; pulmonary consumption 691, acute diseases of the respiratory organs 499, diphtheria and croup 235, diarrheal diseases 185, scarlet fever 80, whooping-cough 65, measles and *roteln* 46, typhoid fever 36, puerperal fever 19, small-pox (Cassel, Dortmund, Essen seven, Coblenz) 10, typhus fever (Königsberg, Elbing, Thorn two, Posen two) six. The death-rates ranged from 14.6 in Stettin to 46.8 in Essen; Königsberg 30.1; Breslau 38; Munich 44.5; Dresden 25.2; Berlin 25; Leipzig 21.7; Hamburg 29.8; Hanover 30.1; Bremen 27.1; Cologne 25.5; Frankfurt a. M. 19.7; Strasburg 36.1.

In the 28 English towns, with an estimated population of 8,457,514, for the week ending March 18th, the death-rate was 22.8. Deaths reported 3699: acute diseases of the respiratory organs (London) 397, whooping-cough 301, measles 153, scarlet fever 85, fever 60, diarrheal 52, diphtheria 23, small-pox (London eight) 11. The death-rates ranged from 13.3 in Portsmouth to 37.7 in Nottingham; Sheffield 18.7; Birmingham 19.4; Leeds 21.3; London 22.7; Bristol 23.1; Liverpool 26; Manchester 30.7.

For the week ending March 18th in the Swiss towns, population 479,934, there were 60 deaths from pulmonary consumption, acute diseases of the respiratory organs 49, diarrheal diseases 16, diphtheria and croup 15, typhoid fever eight, whooping-cough four, puerperal fever two. The death-rates were, Geneva 27.1; Zurich 38.9; Basle 24.4; Berne 28.7.

The meteorological record for the week ending April 1st, in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the U. S. Signal Corps:—

| Date.              | Barom-eter. | Thermom-eter. |       |          |          | Relative Humidity. |            |             |       | Direction of Wind. |            |             | Velocity of Wind. |            |             | State of Weather. <sup>1</sup> |            |             | Rainfall.             |                   |

# OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MARCH 25, 1882, TO APRIL 7, 1882.

ALEXANDER, R. H., major and surgeon. Having reported at these headquarters, will report to the commanding officer, District of New Mexico, Santa Fe, for duty as attending surgeon at district headquarters and post surgeon, Fort Marcy, New Mexico. S. O. 59, Department of the Missouri, March 20, 1882.

TREMAINE, W. S., captain and assistant surgeon. Assigned to duty at Fort Porter, N. Y. S. O. 51, Department of the East, March 24, 1882.

DICKSON, J. M., captain and assistant surgeon. Assigned to duty at Fort Adams, R. I. S. O. 51, Department of the East, C. S.

DICKSON, J. M., captain and assistant surgeon. So much of Paragraph 2, S. O. 51, C. S., as relates to him is revoked, and he will proceed to Fort McHenry, Md., and report to the commanding officer for duty at that post. S. O. 52, Headquarters, Department of the East, March 25, 1882.

GARDINER, JOHN DE B. W., captain and assistant surgeon. To report in person to the commanding general, Department of Arizona, for assignment to duty. S. O. 71, A. G. O., March 28, 1882.

GARDNER, EDWIN F., captain and assistant surgeon. To report in person to the commanding general, Department of the Columbia, for assignment to duty. S. O. 71, A. G. O., March 28, 1882.

ROBINSON, SAMUEL Q., captain and assistant surgeon. To report in person to the commanding general, Department of the Columbia, for assignment to duty. S. O. 71, A. G. O., March 28, 1882.

LAUDERDALE, J. V., captain and assistant surgeon. Having reported by letter to these headquarters, is assigned to duty at Fort Sully, D. T., to which post he will proceed and report for duty. S. O. 47, Department of Dakota, March 27, 1882.

CUNNINGHAM, T. A., captain and assistant surgeon. Granted leave of absence for fifteen days, to take effect on arrival of Assistant Surgeon Artaud at Mount Vernon Barracks, Ala. S. O. 40, Department of the South, April 3, 1882.

CHEERONVILLE, A. V., captain and medical storkeeper. Granted leave of absence for four months on surgeon's certificate of disability. S. O. 77, A. G. O., April 4, 1882.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.—A regular meeting will be held on Monday evening, April 17, 1882, at the Medical Library, 19 Boylston Place. Reader, Dr. C. B. Porter. Subject, A Disease of the Mammary Areola preceding Cancer of the Mammary Gland. C. M. JONES, Secretary.

RUTLAND COUNTY MEDICAL AND SURGICAL SOCIETY.—The quarterly meeting of this Society will be held in Rutland, Vermont, April 12, at the Bardwell House, commencing at 10.30 A. M. Order of exercises: (1.) Report of a Case, Dr. J. Knowlson. (2.) A Case in Obstetrics, Dr. J. H. King. (3.)

Membranous Croup, Dr. L. D. Ross. (4.) Paper, Dr. A. T. Woodward. (5.) Paper, Dr. J. Sanford. (6.) Paper, Dr. H. R. Jones. (7.) Miscellaneous business.

BOOKS AND PAMPHLETS RECEIVED.—University College Course of Practical Exercises in Physiology. By J. Burdon-Sanderson, M. D., LL.D., F. R. S., Jodrell Professor of Physiology in University College, London, with the Cooperation of F. J. M. Page, B. Sc., F. C. S., W. North, B. A., F. C. S., and Aug. Waller, M. D. Philadelphia: P. Blakiston, Son & Co. 1882.

Manual of Dental Surgery and Pathology. By Alfred Coleman, L. R. C. P., Senior Dental Surgeon and Lecturer on Dental Surgery to St. Bartholomew's Hospital. Thoroughly revised and adapted to the use of American Students and Practitioners, by Thomas C. Stellwagen, M. A., M. D., D. D. S., Professor of Physiology at the Philadelphia Dental College. Philadelphia: Henry C. Lea's Son & Co. 1882.

Note on the Microscopic Appearances presented by the Blood of Scarlatina and Typhoid Fever. By J. H. Kidder, Surgeon, U. S. Navy. (With six Photographic Illustrations.) Washington: Office of the Surgeon-General of the Navy. 1882.

Elevation of the Larynx due to Congenital Syphilis. By W. Allen Sturge, M. D. (Reprinted from the Transactions of the Pathological Society of London.)

On the Study of Muscular Atrophy as an aid to the Physiological Investigation of the Spinal Cord. By William Allen Sturge, M. D., Assistant Physician to the Royal Free Hospital. (Reprint.)

Two Cases of Simultaneous Paralysis of both Third Nerves, with Remarks upon Ophthalmoplegia. By W. Allen Sturge, M. D. (Reprint.)

Infant Feeding and Infant Foods. The Anniversary Address delivered before the New York State Medical Society, February 8, 1882. By Abraham Jacobi, M. D., President of the Society. (Reprint.)

Report of the Pennsylvania Hospital for the Insane for the Year 1881. By Thomas S. Kirkbride, M. D., Physician-in-Chief and Superintendent. Published by order of the Board of Managers.

Massachusetts Institute of Technology. Seventeenth Annual Catalogue of the Officers and Students, with a Statement of the Courses of Instruction and a List of the Alumni and of the Members of the Society of Arts, 1881-1882.

Consumption: Is it a Contagious Disease? What can be done to prevent its Ravages? A paper by Bela Cogshall, M. D., of Flint, Michigan, read at a Sanitary Convention at Battle Creek, Michigan, March 30, 1881.

Based Eruptions of Constitutional Origin. By Edward Wigglesworth, M. D., and E. W. Cushing, M. D. (Reprinted from the Archives of Dermatology.)

Epidemic Convulsions. By David W. Yandell, M. D., Professor of Surgery, University of Louisville. (Reprinted from the American Practitioner.)

A Discourse on the Life and Character of Dr. Richard Oswald Cowling. A Valedictory Address delivered to the Graduating Class of the University of Louisville, February 28, 1882. By David W. Yandell, M. D., Professor of Surgery, University of Louisville.

CASES OF POPLITEAL ANEURISM.<sup>1</sup>

BY C. B. PORTER, M. D.

IN order to better appreciate the advantages of the present methods for the treatment of aneurism, it will be well to review in a hasty manner the various measures which have been devised from time to time for its cure. According to Guthrie, "Aetius, who lived thirteen hundred years ago, recommended for the cure of brachial aneurisms, that the artery should be exposed near the armpit; and that two ligatures should be applied to it, a little distance from each other, when the artery should be divided between them. If he had stopped here, he would have performed the modern operation for aneurism, and have left nothing for posterity to discover. He directed, however, that after this had been done, the sac should be laid open and completely emptied, and the artery sought for, and raised with a blunt hook. A ligature was then to be applied above and below the opening into it, and the vessel was afterwards to be divided." "It is very remarkable that he should have combined in one the two methods of proceeding of modern times." "Paulus, a century later, recommended the cutting out of the tumor and its contents after opening it, having previously applied a ligature above and below it." Peter Keiser in 1644 operated upon popliteal aneurism by first opening the sac, then introducing a probe into the upper end of the artery, and applied a ligature above to avoid the diseased and dilated part of the vessel; the cavity was then filled with lint dipped in vinegar and water, and the whole bandaged.

In 1646 Severinus operated upon femoral aneurism by laying open the sac, evacuating its contents, and placing a ligature above and below the opening in the artery.

Mr. Hunter, in 1785, proposed and practiced the operation which justly bears his name, — the ligature of the artery on the proximal side of the aneurism. In his first operation he applied four ligatures on the artery drawn with varying degrees of tightness, but the process of separation was so slow, and their discharge subsequent to the healing of the wound was the source of so much inconvenience, that in his second operation he tied the artery only once.

Without entering into a recital of the various claims to the first proposal to tie the artery on the distal side of the aneurism, which is known in different countries as that of Brasdor, Wardrop, or Desault, and claimed for them by their countrymen respectively, I find that Guthrie says that the operation owes its origin to Brasdor and Desault, but that Deschamps performed the first operation on a femoral aneurism, and Sir Astley Cooper on an aneurism of the external iliac, both of which resulted fatally.

Down to the middle of the eighteenth century pressure directly applied to the aneurism by means of a variety of instruments, bandages, etc., was the usual method of cure, and this was limited to traumatic aneurism at the bend of the elbow, the result of a wound of the brachial artery in venesection. Heister, according to Bellingham, was the first to propose the extension of this mode of treatment to popliteal aneurism,

and although he never put this method into practice, he treated a case of wound of the femoral artery on similar principles, which resulted favorably, though the patient wore afterwards a leather belt, with an iron plate attached, covering the seat of injury. Guitani, an Italian surgeon who flourished about the middle of the last century, was the first who successfully treated popliteal aneurism by compression, his first case being in 1765. "The patient, aged forty, was admitted into the Hospital of the Holy Ghost towards the end of August, 1765, laboring under popliteal aneurism. The tumor was about the size of a large goose egg, was hard and resistant to the touch, had a strong pulsation, and was attended by pain, swelling of the leg and foot, and fever. The patient was directed to remain in bed, was put upon low diet, and bled several times. Towards the end of September the aneurism had ceased to increase, pain was nearly gone, the pulsation had diminished, and the swelling of the limb had in a great measure subsided. Guitani was obliged to leave Rome at this period to accompany the Pope on a journey. On his return, in November, the tumor had not increased, and the edema of the limb having disappeared, he determined to try the effects of compression. Having first covered the tumor with lint, he laid two oblong compresses over its centre, which crossed one another and passed round the limb above and below the knee; another compress was laid along the course of the femoral artery up to the groin. He then took a long roller, three fingers' breadth, with which he encircled the knee, commencing above the centre of the tumor and passing it above and below the joint many times; it was then carried up the thigh to the groin, and for further security he gave it a turn round the body. The whole was moistened with spirits of wine, the patient was bled, and a rigid diet enforced. The bandage was not disturbed for eighteen or twenty days, and then only in order to be tightened, and venesection was repeated whenever the leg or foot swelled." In three months from the first application of the compression the patient left the hospital perfectly well. The treatment in the case quoted extended over a period of three months, and was what would be called direct or immediate compression applied to the aneurismal tumor, and in some cases the whole extremity was bandaged. Treatment of popliteal aneurism by genuflexion was first brought to notice by Mr. Ernest Hart in 1858, though others had used it before him. Flexion seems applicable only to small aneurisms at the bend of the elbow, in the popliteal space, and possibly in the groin. Mr. Lawson Tait says: "The plan by flexion I have tried, and should say of a man who had his aneurism cured by it that he had powers of endurance beyond anything else I know. I have tied up my own leg and the healthy legs of others, and I have not yet seen one who could stand it an hour, while the three men with popliteal aneurism in whom I have seen it tried always let down their legs within ten minutes after they were put up." Treatment by manipulation, by coagulating injections, galvano-puncture, acupressure, is available in cases where other and better methods cannot be used or have failed.

Esmarch rubber bandage and tourniquet have been used a number of times successfully. The first case reported, by Dr. Walter Reid in 1875, was one of popliteal aneurism. The bandage and rubber tubing, having been kept in place fifty minutes, were removed on

<sup>1</sup> Read before the Boston Society for Medical Improvement, April 10, 1882.

account of severe pain, after which compression was applied for two hours, when the aneurism was found to have ceased pulsating. Dr. Lewis A. Stimson, of New York, in the American edition of Holmes's Surgery, gives fifty-two cases treated by this method, with twenty-eight cures, twenty-two failures, and two deaths; that is, twenty-eight successful cases to twenty-four unsuccessful. The subject of treatment of aneurism by compression on the proximal side of the tumor I have reserved to the last, as it is the one to which I wish to call the attention of the Society especially this evening and in conjunction with anesthesia by ether. The first case which I can find of this method, chloroform being used, however, instead of ether, was published in the *Dublin Medical Press*, March 29, 1865, by Dr. Mapother, — a Case of Ilio-Femoral Aneurism cured by Pressure on the Common Iliac and Superficial Femoral Arteries under the Influence of Chloroform. A Signorini's abdominal tourniquet was applied above the tumor one inch above the umbilicus, and a Skey's tourniquet on the common femoral below the tumor. Compression was maintained for four and a half hours without interruption, when, on removal of the instruments, the aneurism was found to be solid and pulseless.

Another case, by the same writer, of popliteal aneurism, was cured by proximal compression under chloroform for seven and a half hours, the flow of blood from the sac being impeded by tight bandaging and elevation of the leg; in other words, proximal and distal compression at the same time. Holmes states that there are "two theories as to the best method of making compression in the cure of aneurism: one that a slow current through the sac is, if not necessary, yet desirable, in order to the deposit of laminated fibrin, . . . and this involves protracted treatment; . . . the other that if the blood can be completely arrested in the sac by compression stopping the circulation absolutely for some hours, the soft coagulum which is at first formed will gradually go on to complete induration and lamination, and the cure will be effected much more speedily and much more surely." It is upon the latter theory that the cases which I have to report to-night have been treated. They are all cases of popliteal aneurism. The treatment was prosecuted from beginning to end under anesthesia by ether.

CASE I. J. H. D., aged forty-nine, entered hospital September 22, 1877, with the following history: One year ago the patient sprained his right leg so that he could not walk for four or five days. Four weeks ago his calf began to swell just below the popliteal space; swelling has steadily increased since then. He is unable to straighten the leg, but holds it slightly flexed.

Examination shows the right leg from knee to ankle to be much larger than the left. On placing the hand over the chief swelling just below the popliteal space distinct pulsation is felt, synchronous with the pulse. Pressure upon the femoral in Scarpa's triangle stops the pulsation. A thrill is also felt with the hand, and a *bruit* is distinctly heard. Patient has considerable pain in leg, especially on movement.

| Measurements.          | Above Ankle. | About Calf. | Above Calf. |
|------------------------|--------------|-------------|-------------|
| Well leg . . . . .     | 8½ inches.   | 12½ inches. | 11½ inches. |
| Affected leg . . . . . | 10½ inches.  | 15 inches.  | 15 inches.  |

Patient was put upon extra diet, with tinct. ferri chloridi twenty drops every three hours. Absolute rest in bed.

September 25th. Patient has great pain, relieved at night by opiates.

September 26th. Some œdema of leg; bandage loosely applied over cotton batting, and leg elevated on an inclined plane.

September 29th. Bandage removed; swelling above ankle three fourths of an inch less than before bandaging.

September 30th. Operation. Patient under ether. Ether given very gradually, tourniquet applied over femoral artery in Scarpa's triangle, the point of pressure being protected by eight thicknesses of cotton batting. Two tourniquets were used, the point of application being changed every half hour. The tourniquet was kept on for about nine hours, two pounds of ether being used during that time. The *bruit* ceased at end of six hours, pulsation at end of eight hours. Emetics (beef tea one ounce, brandy half an ounce) every two hours. Pulse, body temperature, and surface temperature over tumor taken every hour. Patient came out of ether very well, being sensible five minutes after reaching ward.

October 1st. Doing well, no *bruit*, no pulsation. October 2d. Doing well, slight pulsation, no *bruit*. October 3d. More decided pulsation, still no *bruit*. October 4th. Pulsation has returned three days after first compression. Operation. Ether used. Tourniquet applied as before, for six hours. Pulsation ceased at end of four and one half hours. October 5th. No return of pulsation, leg bandaged loosely. October 6th. No pulsation, leg bandaged tightly. October 10th. No pulsation. Patient has but little pain in leg. October 13th. No pulsation. Leg much straighter than before compression. October 15th. Doing well. October 22d. Seventeen days after second compression. Slight pulsation over tumor. Tourniquet reapplied and kept on for nine hours, pulsation then having ceased for two hours. October 24th. No return of pulsation. October 27th. No pulsation, tumor steadily diminishing. December 13th. Patient allowed to get up and walk a little about ward. December 25th. Thirty-one days after last compression. Nothing abnormal about leg except simple œdema relieved by daily bandaging. December 28th. Swelling of knee, patella floats, evidently a large effusion into joint. No pain. Leg placed upon ham-splint, compressed sponge to knee. January 10th. Effusion much reduced. Splint removed. Patient can walk well, only a little weakness. January 20th. Effusion diminishing slowly. January 25th. Discharged well, less than four months from first operation.

CASE II. M. J. L., aged thirty-five. Entered hospital May 31, 1879. Patient is a mill operative, and has always been healthy. About eighteen years ago had a sore on his penis, but he says that it was followed by no eruption, his hair has never fallen out, he has no pain in bones and no nodes. Three months ago he first noticed a bunch in left popliteal space. This came on without known cause, and he cannot remember that he has ever received a blow or strain in that region. The tumor has become more and more painful, and now the leg is almost useless, the knee is slightly flexed and swollen, and the pain keeps him awake at night unless he has an opiate. The tumor is about the size of a small orange, and gives a well-marked expansile thrill

to the touch synchronous with the pulse, and a well-marked *bruit* may be heard and its thrill felt.

| Measurements.        | At Calif.   | Below Patella. | Middle Patella. | Above Patella. |
|----------------------|-------------|----------------|-----------------|----------------|
| Right Leg .          | 11½ inches. | 10½ inches.    | 13½ inches.     | 12 inches.     |
| Left (affected) Leg. | 12½ inches. | 12 inches.     | 14½ inches.     | 14 inches.     |

June 3d. It being decided to attempt a cure by instrumental compression under ether, the patient was etherized at 8.27 A. M., and a pair of Massachusetts General Hospital femoral tourniquets were applied, alternating every fifteen minutes, one tourniquet being kept on until the other was applied. All pulsation was stopped, and heaters wrapped in blankets placed about the leg. When the upper tourniquet was on, the leg became quite purple from pressure on veins about the saphenous opening, but on changing, this almost entirely disappeared. A thick pad of cotton-batting was placed under the block of the tourniquet. Patient was kept under ether until seven P. M., or ten hours and a half, taking two pounds and two ounces of ether. Six nutritive and stimulating enemata were given during the time. Ether given at 8.20 A. M. Tourniquet applied at 8.27 A. M. Tourniquet changed at 8.45 and every fifteen minutes after. Enema of beef-tea, one and a half ounces, milk one half ounce, at 11.20 A. M., one, three, and four P. M. Tourniquet let up for first time at 1.25 P. M. Aneurism still pulsates. Reapplied. Same at four P. M. Reapplied. At five P. M. Enema as before with brandy one half ounce, and urine was drawn. Nothing abnormal about urine except large increase in uric acid. At six P. M. Tourniquet let up. Pulsation. Reapplied. The pulsation was feeble, however, and did not appear for nearly a minute after tourniquet let up. Enema of beef-tea and milk, of each one half ounce, brandy one ounce, quinine two grains at six and at seven P. M.

At seven P. M., pulse and respiration were so rapid, and temperature so high and rising rapidly, and the patient appeared to be in such poor condition, that the ether was stopped and tourniquets removed. No pul-

sation could be felt in tumor, and leg was bandaged with cotton batting from toes to groin. The temperature, pulse, and respirations were taken every hour during the treatment. The temperature, after the first four hours, commenced to rise, and rose quite steadily until it reached 103.8 F., at which point the ether and compression were removed, when it commenced at once to decline and reached the normal point in twelve hours. The pulse marked 180 per minute, and the respirations 48 at the time the thermometer reached the highest point.

June 4th. Day after operation. Patient comfortable this morning. No pulsation in tumor. There is a blister on back of calf and a suspicious looking place on heel. June 7th. Patient kept still in bed. The two places spoken of above were apparently due to burns from heaters and two sloughs are the consequence about the size of pennies. June 23d. Sloughs slowly separating. June 25th. Sloughs removed; dressed with absorbent cotton and resin salve. July 15th. Since last entry ulcers have been healing slowly. Patient has been in bed until within a week. There has been no return of pulsation in tumor. Forty-two days after operation discharged well.

CASE III. E. P., aged forty-three, entered hospital June 21, 1880. Last February patient first noticed a lumpness in left knee, and soon after discovered a pulsating tumor in popliteal space. The tumor continued to grow in size, and became very painful, the pain being felt mostly in the foot. He put himself under the care of a clairvoyant, under whose treatment he said he was cured so that he was able to go about, and that six weeks ago he was walking. At that time the tumor suddenly started up, and increased rapidly in size. Was confined to bed, and kept the knee flexed. Now there is a large pulsating tumor in left popliteal space, occupying the entire space, and extending up into thigh and down into calf of leg, making the tumor about six inches in length. He keeps the knee flexed all the time. General condition of patient is bad; he is very weak, and has no appetite, but the condition of the aneurism seems to demand immediate treatment.

June 25th. Operation under ether; commenced with ether at 9.30 A. M.; thigh tourniquet was put on femoral artery at 9.50 A. M., the tourniquet was put on just tight enough to stop all pulsation in the aneurism; a pad of cotton batting was placed over the thigh; the tourniquet was shifted every half hour. Nutritive enemata were given every two hours, but only one was retained. Later, the patient was allowed to partially come out of his ether, and at these times he was given brandy and milk by the mouth. After he had been etherized about six hours there was a marked change, pulse was very weak in right, and could not be felt at all in left wrist; the respirations were quick and labored. Ether was stopped at eight P. M.; the tourniquet was let up to see if the tumor pulsated, at one, four, six, and eight; at six there was only a feeble pulsation, at eight P. M. there was none; patient came out of ether well, and was perfectly conscious, but was very restless, and complained of being tired; no pain; foot was wrapped in cotton, and a heater put to it as it was of a suspicious purple color and very cold; patient was stimulated, and given as much nourishment as he could take during the night, pulse became stronger, and it was perceptible in left wrist.

June 26th. Patient conscious, but delirious at times; very restless; was failing fast, and died the second day

after operation from exhaustion, the leg and foot looking badly, though gangrene was not evident. No autopsy allowed.

CASE IV. E. K., aged thirty-nine, entered hospital April 14, 1881. In popliteal space was an aneurism as large as a large orange. The expansile pulsation was very marked. Had never been treated. Foot and leg were in good condition. Some pain lately from pressure of the tumor.

April 15th. All preparations being made, ether was started and tourniquet applied at 11.30 A. M. Nourished by rectal injections of brandy and milk. Pulse, respirations, and temperature taken half hourly. The tourniquet was let up every three hours, and pulsation found until twelve, midnight. The tourniquet was kept on until one A. M., thirteen and one half hours. Four pounds of ether were used, of which he took not more than one half. His temperature rose from 96° F. to 99° F., and stayed there; pulse from 80 to 90; respiration from 25 to 30. At twelve, midnight, violent hicough came on, and ether was stopped, and hicough relieved by morphia, one eighth of a grain subcutaneously. April 16th, at two A. M., pulsations began again, but his condition did not warrant reapplication of tourniquet; stimulated; very little pain during the day. April 18th. Feeling all right; no sloughs from pressure or heaters. April 19th, 5.30 P. M. Tourniquet applied, examined every two hours; pulsation stopped at 7.40 P. M.; tourniquet continued until nine P. M.; no pulsation again until 11.30 P. M., when it began, but not as strongly as at first; the tumor seems much more solid, and there are evidences of collateral circulation beginning. April 20th, five days from first operation. Feeling well, and of good courage; ether began at 4.50 P. M.; pulse did not rise above 84, temperature not above 99.5° F., and respirations not above 28; took about two pounds of ether; took brandy and milk by mouth, coming out of ether enough for that; tumor pulsated until five A. M. of April 21st; tourniquet kept on until seven, then Esmarch applied; there was no pulsation in tumor until two P. M., then very slight; the Esmarch was firmly applied, but gave so much pain ether was necessary until ten P. M., there was then pulsation. April 22d. Patient kept leg flexed, controlling the pulsation, but this was so painful it was frequently necessary to extend the leg. April 23d. Somewhat discouraged and used up from ether; collateral circulation well developed; leg somewhat swollen, but not oedematous. April 25th. Tourniquet applied at ten A. M.; borne for two hours without ether; pulse did not rise but once above 90, temperature not above 99° F., and respirations not above 30; took good quantities of milk and brandy by mouth; tumor pulsated until April 26th, five A. M.; tourniquet was kept on until eleven A. M., twenty-five hours; the tumor kept perfectly solid, but the collateral circulation was so developed that the surface of tumor was covered by arteries, whose pulsation gave movement to the tumor.

April 27th. Feeling rather weak from prolonged etherization, but coming up well under stimulants; no signs of sloughing. April 29th. Swelling of leg diminished; feels well. May 1st. Impossible to tell if tumor is pulsating, or if pulsation is due to posterior tibial. May 3d, seven days after last compression. It was decided that there was faint pulsation in tumor, which is very hard, and diminished to about the size of a very small orange; there is none of the expansile

character about it; there are several large arteries running over the face of it. May 12th. Given tourniquet, which he applied himself, keeping up pressure from one half to two hours in one place, and then varying it; the pain is severe, but he pluckily bears it. May 14th, five P. M. The above treatment has been kept up since twelve, and now on letting it up there was no pulsation; immediately reapplied. May 15th. Pulsation reappeared as soon as tourniquet let up; continue tourniquet. May 22d, thirty-seven days after first compression. Tourniquet let up, and not resumed. June 12th. Since last record there has been no resumption of pulsation. June 22d. Goes about in rolling-chair. July 1st. Goes about on crutches.

CASE V. J. P., aged sixty-five, entered hospital April 28, 1880. Four months ago patient was accidentally shot, the bullet passing through his right leg, just above the knee, to the inner side of the bone, entrance in front and exit behind. It was not until one month after the accident that he first noticed a pulsating tumor in the course of the femoral artery, at its lowest point. At the advice of his physician he kept absolutely quiet in bed, and applied pressure over the femoral artery, part of the time with his thumbs, and part of the time he had relays of men to take turns at pressing. He also used a shot-bag. Now there is a tumor on inner and posterior aspect of thigh, just above the knee, and over the inner ham-strings. The tumor is hard, does not pulsate, measures sixteen and one fourth inches around at largest point. Knee is flexed at a right angle.

May 1st. Tumor is diminishing in size; kept in bed, and not allowed to get out under any circumstances. May 10th. Flannel bandage has been applied from the toes to above tumor a few times, but it is so uncomfortable that he will not keep it on for any length of time. June 10th. Patient allowed to go about in a wheel-chair; condition of aneurism as before. June 13th. Patient given crutches. June 30th. Discharged; the tumor solid, and slowly diminishing in size.

In the method described in the cases reported, the principal dangers and obstacles to the treatment of aneurism by compression are either done away with entirely or reduced to the minimum. The pain of pressure sufficient to control pulsation can be endured without anaesthesia only for a short time by the most heroic. The danger of slough from continued pressure is avoided by the use of two tourniquets, shifting the point of pressure frequently, and by a thick pad of cotton batting placed between the block of the tourniquet and the skin, thus supplying elastic compression, which I consider a very important adjuvant. The shock and exhaustion of the operation is reduced to the minimum by anaesthesia with stimulating and nutritive enemata. The latter, in Case III., which terminated fatally, were not retained. Surrounding the affected leg with heaters supplies the warmth which is essential to its vitality, and which for the time being is reduced by the diminished supply of blood.

To briefly summarize: Case I. required the tourniquet three different times, three, six, and nine hours respectively, in all, twenty-four hours.

Case II. Tourniquet ten and a half hours.

Case III. Tourniquet eight hours and ten minutes.

Case IV. Tourniquet five times, thirteen and one half, three and one half, fourteen and one half, nineteen, and five hours respectively, with a few short ap-

plications without ether, in all, fifty-five and one half hours.

Four complete recoveries and one death in a bad case, which would probably have resulted fatally whatever had been done; though in treating another similar case, I think I should do the old operation of laying open the sac, evacuating the contents, and tying the artery above and below the tumor, with the addition of antiseptic precautions.

The method of proximal compression seems applicable to circumscribed aneurism of the extremities; the method of laying open the sac and tying above and below, to diffused or dissecting aneurism where the sac has ruptured; and one or the other should in most cases supersede the Hunterian operation.

In aneurism of the iliacs, the carotid or subclavian, or both of the latter conjoined, Brasdor's operation, distal ligature, or distal compression are the expedients available by the surgeon, all operations with the knife to be performed with the strictest antiseptic precautions.

## RECENT PROGRESS IN ORTHOPEDIC SURGERY.

BY E. H. BRADFORD, M. D.

### SYPHILIS OF THE JOINTS.<sup>1</sup>

RICHET, in 1853, in a monograph, described the effect of syphilitic virus acting upon the joint and altering the synovial membrane and the bony ends of the joints. The bone is affected at the later stages of the disease, and ankylosis may result. Brochin, Simon, Virchow, Hurt, Volkmann, Lancereaux, reported cases, the latter demonstrating the lesions by autopsy. He found the larger joints more liable to be affected than the smaller, and that the knee-joint is attacked by preference. The lesion in the subsynovial cellular tissue is regarded as being gummatous; the synovial membrane was not the only part affected, the cartilages being eroded in places, and a serous effusion in the joint being also noted.

Syphilitic arthropathies develop slowly; they do not tend to suppuration, and under specific treatment may end in recovery. A form of syphilis of the joint is to be met where the disease originates in the bone, this being followed by a hydrarthrosis.

Lücke met with well-marked cases in syphilitic patients, where thickening of the capsule and increase of the synovial fluid was found, the whole disappearing under mercurial inunction. The course of these cases resembled that of the ordinary chronic fungous joint inflammation.

Oedmasson and Risel have both had opportunity of examining cases of the affection, post mortem. The former found among other characteristic syphilitic bone lesions, — namely, extensive osteitis, periostitis, exostoses, necrosis, — a synovitis of the knee. The latter found, besides extensive evidence of ostitis, gummosa in the fingers and toes, hyperplastic enlargement of many of the long bones, cicatrices of old ulcerations of the cartilages of the size of a pen. In a second case the anatomical appearances were those of an extensive caries of the knee-joint, a condition which developed during life gradually, without suppuration.

Fournier states that the specific pseudo-rheumatism

is to be distinguished from ordinary rheumatism chiefly by the mildness of its course.

Zeissl, from his extensive experience, is led to believe that the specific joint affections are quite rare. On the average one thousand syphilitic patients pass annually under his observation, and frequently no case is seen during the whole year. In the few which he has observed, the knee and ankle were the joints most frequently affected; the acromial, elbow, and wrist joint were less frequently seen. The hip joint was never affected. Some of the joints were recently attacked and accompanied by severe pain; others were chronic, characterized by hydrarthrosis, tumor albus, and degeneration of the joint, and sometimes complete ankylosis. In a majority of the cases, he found antisyphilitic treatment to be followed by no special benefit.

Kohn distinguishes between the syphilitic congestion of the joint (the arthritis subacuta syphilitica) and a chronic form, which develops in the course of the disease. The first is accompanied by more pain than the second; the latter frequently leaves behind it crepitation on moving the joint, which may be so marked as to be heard at a distance.

According to the observations of Voisin, the joint pains which are observed in the first stages of syphilis are to be classed as a true arthritis. The true hydrarthrosis develops at a later stage. Sometimes the inflammation of the joint follows a contusion.

Similar to this specific synovitis is the syphilitic inflammation of the sheaths of the tendons. This appears usually in the secondary stages of the disease.

Gies reports an interesting case (with autopsy) of a peculiar arthropathy of the knee-joint occurring in a syphilitic patient, where deep destruction of the cartilages was to be seen, and a thickening of the synovial membrane. The appearances were different from the ordinary fungous disease, resembling more those of arthritis deformans, from which latter it differed in the absence of alterations in bone.

Gies classifies the specific joint affections as —

- (1.) Acute, occurring during the first stage of syphilis.
- (2.) The arthropathies accompanied by gumma.
- (3.) Subacute affection of the joints without marked evidence of gummata.

### TREATMENT OF OLD FRACTURE OF THE VERTEBRA.

Küster<sup>2</sup> adds to König's cases of fresh fractures of the spine treated by the plaster-of-Paris jacket four less recent cases treated successfully by extension.

He believes that recovery is more readily and more completely gained by this treatment than by simple confinement to bed. He advises an attempt at reposition under ether, to be made by extension or direct pressure. If reposition is successful, extension should be continued.

The application of a plaster jacket is attended with difficulty and danger on account of sloughs; a felt jacket which is adjustable may possibly be of more advantage.

### ON THE SO-CALLED RUPTURE OF THE INTERNAL LATERAL LIGAMENT OF THE KNEE JOINT.<sup>3</sup>

Jersey is of the opinion that the injury which is called the rupture of the internal lateral ligament of

<sup>2</sup> Archiv f. Klin. Chirurgie, 1881, page 841.

<sup>3</sup> N. Y. Med. Record, June, 1881, page 663.

<sup>1</sup> Gies, Deutsche Zeitschrift f. Chir., 1881, page 605.

the knee is in reality a separation of the tuberosity of the internal condyle of the femur.

As a support of this view, he quotes the results of experiments on cadavera as follows: in three adult cadavera a separation of the tuberosity, and in two young cadavera a separation of the epiphysis of the tibia, followed forcible turning the leg out, the femur being held firmly.

#### RUPTURE OF THE TENDON OF THE PATELLA IN THE COURSE OF CHRONIC RHEUMATISM.<sup>1</sup>

This accident is recorded as having happened to a patient thirty-eight years of age, who ten years before had suffered from a severe attack of acute rheumatism; a lighter attack followed later, and again another six months before the accident. The tendon was ruptured on the first attempt at walking after this attack, on making a step upwards, the separation taking place directly under the patella.

The treatment employed was simply an appliance to aid in locomotion.

#### PRIMARY DISEASE OF THE SEMILUNAR CARTILAGE OF THE KNEE-JOINT.

Kocher<sup>2</sup> reports three cases of circumscribed fungous disease of the internal meniscus. In one of these, ignition-puncture and removing the granulations by scraping resulted in recovery; in two extirpation of the affected meniscus was followed by a cure, with active motion of the joint. In a fourth case the external semilunar cartilage was removed on account of chronic inflammation and a relaxed condition which interfered with locomotion. The operation resulted in healing by first intention.

#### LUXATION OF THE SEMILUNAR CARTILAGE OF THE KNEE-JOINT.

Nicoladoni reports a case of this unusual affection, which he says is frequently confounded with a loose cartilage. Observations are on record where the meniscus could be readily felt as dislocated, and where after reduction, the symptoms disappeared.

In the writer's case (in which the symptoms followed an accident in the gymnasium) the joint was cut down on in the expectation of removal of a loose cartilage, when it was discovered that the semilunar cartilage caused the difficulty, and the synovial membrane was stitched together in the hope that the contraction of cicatrization would fix the cartilage. This did not take place, and the patient, after a ready recovery from the operation, was in no way better of his previous symptoms.

On a dissecting room cadaver a similar lesion was found, which on investigation was found to be a loosened and altered semilunar cartilage.

#### CONGENITAL SPASTIC CONTRACTURE AND STIFFNESS OF THE LIMBS.<sup>3</sup>

Little described a pathological condition under the head of congenital spastic rigidity of the limbs. Seelegmüller and Erb rediscovered the affection under the name of spastic spinal paralysis, classifying as well as investigating it more thoroughly than had been done before. Rupperecht has recently called renewed attention to this peculiar state. It is not a paralysis or

paresis, but proper locomotion is interfered with, for the reason that when a group of muscles act voluntarily, the antagonists at the same time are placed in a state of spasm. There is a marked increase of the tendon reflex. The spasmodic condition relaxes during sleep. The pathology of the affection is as yet not fully understood; it is clearly the result of a defect or atrophy in the spinal cord. It is not a paralysis *stricto nomine*.

The diagnosis is easily made by any one who has seen any case of the same affection. It is not possible to confound it with the ordinary infantile paralysis, but it may be difficult to distinguish it from the acquired form of cerebral or spinal paralysis unless the clinical history is clearly understood. The prognosis is necessarily unfavorable, but a certain amount of improvement may be gained.

The best method of treatment is tenotomy of the tendo Achillis and adductors, if necessary, followed by fixation in a corrected position by apparatus or plaster-of-Paris bandage. After this a relapse does not appear to take place. A perfect recovery is not to be expected.

Tenotomy in certain cases is apparently not essential, but treatment without it must be carried on for a long time.

#### SPONDYLOLISTHESIS AFTER FRACTURE OF THE SPINAL COLUMN.

Leser<sup>4</sup> describes a unique case of this affection which is characterized by a displacement of the spinal column into the pelvis. The patient was a boy fifteen years old, and was run over by a wheel of a wagon passing over the lumbar vertebra just above the pelvis. Four months later the boy had so far recovered as to be able to go about on crutches, the symptoms of paralysis which had followed the accident having gradually disappeared. There was marked lordosis; the spinous process of the last lumbar vertebra was not felt; the gait when the patient attempted to walk, which he could for a few steps, was like that of a patient with congenital double dislocation of the hip joint. There was paresis of the splinter of the rectum, and on examination by the finger per anum, a large, broad, bony substance could be felt, five centimetres in front of the tip of the sacrum; this was rounded in front and flattened on the under surface, and was manifestly the vertebra forced forward and downward. By pressing still further upwards with the fingers, the intervertebral substance could be felt. On suspending the patient, examination by the rectum showed that there was firm union of the displaced fragments. A felt jacket was applied and this enabled the patient to lay aside the crutches in walking.

#### PATHOLOGY OF JOINT DISEASES.<sup>5</sup>

The question of the connection between tubercle and the chronic joint affections continues to excite discussion. There can be no doubt that military tubercles are formed in great numbers in the affected bones and joints; to reason, however, from this that the disease is essentially tuberculous is to pass into the region of theory.

König classifies "joint-tuberculosis" under three heads:—

<sup>1</sup> Mém. Gaz. des Hôpitaux, 1881, No. 1121.

<sup>2</sup> Centralblatt f. Chirurgie, November 5, 1881.

<sup>3</sup> Rupperecht, Klin. Vorträge, No. 198.

<sup>4</sup> Deutsche Zeitschrift f. Chirurgie, 1881, page 106.

<sup>5</sup> Sonnenburg, Archiv f. Klin. Chir., 1881, page 789.

First, where the foci are developed independently, without the presence of any known general tuberculosis; second, where the affection of the joint follows a general tuberculous condition which has resulted from foci in the lungs, etc.; third, where the tuberculosis of the joint gives rise to a general affection. Deaths are much more frequent in the second group than in the third.

Sonnenburg agrees with Volkmann that tuberculosis of the joint readily inoculates itself locally, but only under certain conditions develops into general tuberculosis. Heredity undoubtedly plays an important part in the causation of tuberculosis. Volkmann is of the opinion that patients with fungous disease of the joints are almost invariably from families where tuberculosis or scrofula is inherited. Some of these die later of tuberculous process of other organs; this is especially true of younger children, but a proportion by no means small recover and remain well. Those writers who, with Schüller, believe in parasitic infection as the cause of fungous joint disease necessarily lay little stress on the influence of hereditary taint, but the bulk of opinion is at present decidedly in favor of the belief that joint-tuberculosis is more prevalent in families where the taint is hereditary than where the affection may be said to develop *de novo*. In such cases, also, the liability to generalization of the disease is greater.

Where there is no hereditary taint, recovery from joint-tuberculosis is not so uncommon as is thought by many German writers, not only after excisions, but also after expectant treatment. This, according to Sonnenburg, is a more prevalent opinion in England and America than in Germany, and therefore the prognosis of expectant treatment appears more favorable in the minds of English and American surgeons than among the German. So marked is this that König is led to query whether tuberculous hip disease in England is a different variety from that met with on the Continent, — a question which the writer suggests may be due to the possible fact that hereditary tuberculosis may be less prevalent in the other than in the continental countries, and also because the external conditions are generally better in England and America.

Sonnenburg shows, from quoted observations on undoubtedly localized joint-tuberculosis, that in many cases it is impossible to distinguish, from the anatomical appearances, the local from the general affections, and concludes that there is no other sure criterion of true tuberculosis than its infectiousness; but the theory of Schüller and others that joint-tuberculosis is the result of a specific virus, due to a particular micro-organism, has been by no means confirmed, and must be regarded at present as a pure theory.

The writer concludes that it will be better to entirely discard the term tuberculosis in speaking of this class of cases, using in its place that of scrofulous inflammation with or without the development of tubercles, and that tubercles are to be regarded as by no means the chief factor in the development of the disease, although probably an important one. Progress in the future may be looked for when we are able to diagnose the real tuberculous cases from the pseudo-tuberculous, regulating treatment, that is, radical surgical intervention or the reverse, accordingly.

Eighty-six cases of rickety curved limbs are reported by Albertini e Panzeri,<sup>2</sup> as treated by osteoclasis or os-

teotomy; forty-five cases were of genu valgum, eleven of curvature of the tibia, two cases of curved femora, and three cases of deformed callus in the femur.

The knock-knees were treated by *redressement forcé*, except in six cases according to Tillaux' method. The curved femora were straightened by osteoclasis, as was also the deformed callus. The osteoclasis was always performed with hand power; in cases where this was not sufficient the osteotome was preferred to the osteoclast. One patient died of pyæmia, the other cases, presumably, were successful.

#### CLUB-FOOT.

Wolff<sup>2</sup> describes a method of treating club-foot by means of bandages soaked in "water-glass" (silicate of potash). The method is as follows: After applying adhesive plaster around the foot and leg in the manner described by Sayre, thin cotton bandages are laid around the foot from the metatarsophalangeal joint to the tuberosity of the tibia, and over this a double layer of the same bandage soaked in silicate of potash; over this a temporary plaster bandage is placed, and while this is becoming hard the foot should be forcibly straightened by the hands of assistants, and the position held until the bandage is perfectly hard. The patient ordinarily suffers more or less pain the night following the application; this diminishes, and on the third day usually has disappeared. By this time the temporary plaster bandage can be removed, leaving the silicate hard underneath. This is facilitated by wrapping the whole in moist cloths, which softens the plaster to a degree, but has no effect upon the silicate. A new layer of silicate bandage is then applied over the original one, rendered rough by the removal of the plaster of Paris. The patient is able to walk about for a long time with the appliance, which can be covered with a stocking and worn inside a shoe.

#### REMOVAL OF LOOSE CARTILAGES FROM THE JOINT.<sup>3</sup>

The methods of removal of loose cartilages are two: (1.) The old open incision, first introduced by A. Paré, discarded by many later surgeons (among these was B. Bell, who preferred amputation of the thigh). Antiseptic precautions have of late given new life to this mode of procedure, but before this mode of dressing was introduced many successful cases resulted from direct incision. (2.) Subcutaneous extraction (*opération en deux temps*).

This latter is preferred by the writer, who in two successful cases made use of the method of Goyrand, which he found, however, not free from difficulties. The foreign body is pushed into the upper external cul-de-sac, and held by the finger of an assistant under the triceps tendon, and by the help of another aid kept from slipping upwards. An incision is then made with a tenotome in the subcutaneous tissue directly under the synovial cavity, and in the synovial wall directly under the foreign body, which is forced out into the cellular tissue; two weeks later the loose cartilage is removed by direct incision. The difficulties of the second step, namely, removal of the cartilage from the tissue, were such that the writer is doubtful whether a direct incision might not be preferable.

Richet<sup>4</sup> mentions that he has several times seen sur-

<sup>2</sup> Archiv f. klin. Chirurgie, page 375, 1882, 27th Band.

<sup>3</sup> Catrin, Gaz. Hebdom., September 23, 1881, page 610.

<sup>4</sup> Fr. Med., July 12, 1881.

<sup>1</sup> Centralblatt f. Chirurgie, No. 37, 1881.

geons of ability fail in attempting to remove a loose cartilage according to this method. He therefore prefers direct incision with antiseptic precautions. The cartilage is to be fixed by the aid, cut down on, and held by a hook between the lips of the incision. After freeing the surrounding tissues the pedicle is cut (if it is present), and compression is made to prevent the entrance of air into the articulation. In Richet's experience antiseptic precautions had not always conferred the immunity from secondary inflammation he had expected.

Gaujot<sup>1</sup> believes that surgeons have generally discarded the subcutaneous method in favor of the open incision, partly on account of the uncertainty of the former, and partly because statistics appear to show that the mortality at present from the subcutaneous incision is greater than from the direct incision (13 per cent. and 7.05 respectively). Gaujot has collected fifty-four cases where the results were as follows: twenty-nine dressed with the Lister dressing, twenty-seven recovered, two died; three, the simple Guérin cotton dressing, all recovered; three, cotton dressing with antiseptic precautions, two recovered, one died; seventeen with dressing to exclude air, but not a strict Lister dressing, one died, the others recovered. (In these latter cases great care was taken in the operation to prevent infection.) According to the writer, if the foreign body is a result from a proliferation of the synovial membrane, and not a portion of the cartilage separated by an injury, a relapse may be expected.

#### TRANSPLANTATION OF TENDON.

Nicoladoni,<sup>2</sup> in a case of *pes calcaneus* with paralysis of the calf muscles, "grafted" the peroneal tendons on to the stump of the tendo-Achillis, which had been divided. Healing by first intention followed, and the patient was found to have gained in walking and in plantar flexion.

Boger<sup>3</sup> describes a method of fixing the head in cervical curies. An ordinary plaster jacket is placed around the trunk; in this two strips of bent iron are incorporated, extending from the trunk to the head; this latter is fixed to the iron by plaster bandages, which should extend far enough down on to the head to hold it firmly. The writer claims that the head can be secured in this way so firmly that when strips of adhesive plaster applied to the head for suspension are cut the extension is still maintained.

## Hospital Practice and Clinical Memoranda.

### TWO CASES OF CONGENITAL IRIDEREEMA, WITH LAMELLAR CATARACT IN ONE AND DISLOCATED CATARACTOUS LENSES IN THE OTHER.

BY GEO. C. HARRAN, M. D.,

Surgeon to Wills Eye Hospital and the Eye and Ear Department of the Pennsylvania Hospital.

CASE I. N. J. M., aged twelve, says that he knows of no defect in the eyes of any other member of his family in this or preceding generations, except that his mother is "short-sighted." He is of medium size and, except his eyes, well developed.

His vision is  $\frac{6}{60}$ , and is not improved by glasses or the stenopæic hole. There is no photophobia, and he sees better in a bright light than in a subdued one. The cornea are clear, but perhaps very slightly below the normal size, though a constant and decided nystagmus makes it impossible to measure them accurately. The eyes are free from irritation, and their tension is normal. There is not a vestige of iris in either eye

There is well-marked lamellar cataract in both eyes. In each lens there are two opaque layers with clear lens matter intervening between them, beautifully seen by oblique illumination. Only occasional and partial glimpses of the fundus can be obtained, but the choroid seems normal. There is not sufficient vision for any satisfactory test of the accommodation.

CASE II. J. B., a well-grown boy of thirteen years, has rather prominent eyes, with full-sized cornea, and normal tension, but the iris is entirely absent in both. In the right eye the cornea is quite clear, and, though there are floating opacities in the vitreous, the details of the fundus can be seen fairly well. The lens, which is of normal size, is opaque and white, and is dislocated upwards, so that only about its lower half is seen beneath the corneo-sclerotic junction. The ophthalmoscope shows a hypermetropia of  $\frac{1}{2}$ , which, assuming  $+\frac{1}{2}$ , to represent the loss of refractive power induced by aphakia in the emmetropic eye, indicates a structure of the ball corresponding to a myopia of  $-\frac{1}{2}$ . The choroid and retina appear normal in structure, but the optic disk is atrophied and greatly distorted, the vertical diameter being twice that of the horizontal, and the retinal vessels crowded to its inner edge; vision is only quantitative. There is no nystagmus.

In the left eye there is a diffused haziness of the cornea, which, together with a greater opacity of the vitreous than in the other eye, makes the details of the fundus invisible. The lens, which presents the same form of cataract as that in the right eye, is still further out of position, and only a narrow edge of its periphery extends below the margin of the sclerotic. The lenses seem to be held in their unnatural position by some attachment of their upper margins, while the lower are free, and they swing backwards and forwards, as if on hinges, with the movements of the balls. In the left eye the lens has caused an absorption of the tissues, against which it rests until the choroid has disappeared from above it, and the sclerotic is very much thinned and slightly staphylomatous. When the cone of light, concentrated by a convex glass, is thrown upon it from below, the outlines of the lens become distinctly visible through the sclerotic.

Though irideremia (iris and eremia, absence), or aniridia, is an extremely interesting anatomical curiosity, it can scarcely be said, in the present state of our knowledge, to teach any useful lesson in embryology or pathology. Numerous hypotheses have been suggested to account for its occurrence, but most of them are more fanciful than philosophical, and perhaps none of them are more rational than that maintained long ago by Von Ammon, who, in view of the late appearance of the iris, after the choroid is fully formed, considered its absence as simply the result of an arrest of development of the uveal tract. It is a curious fact that this anomaly is almost invariably symmetrical. According to Manz,<sup>1</sup> but one case has been reported in which it occurred in one eye only. Another point of interest in the history of this defect is its decided tendency to hereditary transmission. A number of cases of inheritance have been reported; one (quoted from Von Ammon by Lawrence) in which one member of the first generation was affected, three of the second, and five of the third.

The fact that cataract is very generally associated with irideremia has given some support to a suggestion that the iris is concerned in the nourishment of

the lens, and to an ingenious theory of the causation of irideremia, which supposes that the iris has been crowded out as it were, by the lens remaining too long and too closely in contact with the cornea during embryonic life. This coincidence of cataract with irideremia is, however, not constant, as cases are recorded in which the lens was transparent. One is reported by Dr. Reuling,<sup>2</sup> in which vision was sufficiently acute to enable the observer to determine that the power of accommodation was unimpaired.

The normal intraocular tension found in cases of irideremia has been adduced to prove that the aqueous humor is not secreted by the iris, but chiefly, if not entirely, by the ciliary processes. In the rabbit the ciliary processes are connected with the iris, and when both are removed the eye becomes very soft and the aqueous humor is never regenerated.<sup>3</sup> This, so far as it goes, gives support to the advocates of sclerotomy instead of iridectomy in glaucoma.

Partial congenital luxations of the lens are usually upwards, as in Case II., and frequently occur without defect of the iris. In the left eye of this patient the lens is so far out of place that it would be entirely concealed if the iris were present, and this case might then be readily mistaken for one of the very rare anomalies of congenital aphakia.

After the reading of the preceding paper, Dr. W. F. NORTON said:—

"Through the kindness of Dr. Harlan, I have had an opportunity of making an examination of the eyes of the patients whose cases have been described. On first inspection of one of the cases I thought I could detect a slight peripheral remnant of the iris, but more careful examination, aided by the ophthalmoscope (oblique light), showed that every vestige of iris was wanting, that this appearance was due to the shadow cast by the limbus conjunctivæ corneæ on the periphery of the anterior chamber.

"It has occurred to me that at least some of the cases which have been reported in the older books as partial irideremia, might possibly be due to this similar appearance in the days when the above-mentioned methods of examination were unknown."

## BOSTON CITY HOSPITAL.

SURGICAL CASES IN SERVICE OF DR. GEORGE W. GAY.

REPORTED BY R. A. KINGMAN.

### I. PERINEAL SECTION.

THOMAS M., forty-four years old, was admitted with a stricture of the urethra and fistula in the perineum. Had gonorrhœa twenty years ago, and for the last eight or nine years has noticed his stream of urine constantly diminishing in size. Two years ago he had two swellings appear just below the scrotum, which finally burst and formed permanent openings, through which urine has escaped ever since.

September 17th he was etherized, and the urethra thoroughly explored. It was found to be extremely irregular in shape, and to contain several very tough strictures, which would admit only a small bougie.

After enlarging the meatus by cutting, a Keyes's straight staff was introduced and carried down to the

<sup>1</sup> Handbuch, Augenheilkunde II., page 90.

<sup>2</sup> Am. Journ. Med. Sci., January, 1875.

<sup>3</sup> Deutschman, Grafe Archiv, v., 26, No. 3.

perinaeum, where an incision one and a half inches long was made upon it. A probe-pointed director was carried through this opening into the bladder. The Otis operation of cutting and stretching was now performed upon the anterior portion of the urethra, and a No. 16 English steel sound passed without much difficulty. A silver catheter was introduced through the entire urethra into the bladder and strapped in. Perinaeum dressed with a poultice.

September 20th. Catheter removed. After September 24th no urine was passed through the perineal incision, and patient could make a good stream through the penis. He was catheterized every two or three days, and the bladder irrigated with warm water, on account of cystitis, from which he had been suffering for a long time.

October 6th a No. 15 steel sound was easily passed, and October 10th he was discharged, the perineal wound being healed.

## II. TREPHINING FOR EPILEPSY.

Robert M., sixteen years old, was born in New Brunswick, where he has always lived, having come to Boston only a few days since for the express purpose of undergoing the above operation. He was admitted to the hospital September 17th, and was placed in the large tent ward.

Four years ago, as he was stooping with his hands thrust backwards between his legs, a boy caught hold of his hands and pulled him so that he fell forwards, striking his head on a projecting knot in the wooden floor, and losing consciousness. Shortly after he began to have epileptic fits, which continued for a year, occurring sometimes as often as three times a week, but from which he has been free for the past three years.

Two months ago, without any fresh cause, he began to have a sense of oppression and tenderness in a circumscribed spot on the top of his head, with a growing inability to sleep. His mental condition has undergone a marked change, so much so that at times he appears quite insane. During the few nights he was in the hospital before being operated upon, he was extremely delirious, sitting up in bed, raving and crying till after midnight, when he would become quieted under the effects of chloral and bromide of potash. Complained of severe headache. He and his friends anticipated a return of the convulsions. His memory and temper were much impaired.

September 23d he was etherized, and a careful examination of the skull was made. It appeared somewhat flattened on the vertex, but no depression could be discovered. The place in which he localized his disagreeable sensations and tenderness was exactly in the middle of the vertex, and accordingly Dr. Gay trephined at this point, removing a piece of bone one inch in diameter. The operation was done with full Lister precautions, a powerful carbolic spray being used, and the head being subsequently almost entirely enveloped in carbolic gauze. So far as could be determined, there were no abnormal changes in either the bone or the dura mater. Although the operation was performed directly over the longitudinal sinus, the membranes of the brain were uninjured. The flaps were merely allowed to fall together, no sutures being inserted.

The next day the head was redressed under the spray, and was in a good condition. He says he feels much better than before the operation.

Ice cap ordered to head. The wound was dressed

daily for a week, and then every two days. October 3d, wound was healed, and head was dressed merely with cotton batting.

October 8th, sat up and went out-doors. Since the operation he has had no pain, has slept well, and seems bright and intelligent. Temperature never higher than 98.3° F. Two days after operation, was sitting up in bed reading.

Discharged October 10th, free from his old symptoms.

This boy continues perfectly well up to the present date, April 6, 1882, according to a letter this day received from the family.

## III. TREPHINING FOR EPILEPSY; NO IMPROVEMENT.

William J. McG., twenty-three years old, single, was admitted for an operation on a phimosis which he claimed to be of traumatic origin. He gave no history of venereal disease, or of any important sickness. His speech was noticed to be slow and slightly hesitating, but no importance was attached to it.

A week after the operation of circumcision he experienced a severe convulsion of marked epileptic character, which was followed by a considerable period of unconsciousness. During the remainder of the day he complained of headache and of "feeling nervous." Occasional trembling and twitching of the limbs was remarked. On being questioned he admitted having had similar attacks previously, during which he had fallen to the ground, and after which he had found his tongue wounded. He recalled an injury received two or three years ago from a stone which struck him on the head and produced a large wound. According to his story there was a fracture of the skull at the same point, and on examining the head an apparent depression was felt under the cicatrix. It was located near the junction of the sagittal and lambdoidal sutures. About six hours after the first fit he had another one. Urine normal, except faint trace of albumen. His face assumed a flushed and somewhat livid appearance, and the mouth was drawn slightly to the right side.

Two weeks later the same condition of things persisted, though no more fits had occurred. The mind was sluggish and the memory poor. At that time the patient desired, and the friends consented to, trephining as offering a possible means of relief, medical treatment having hitherto been unavailing. Accordingly Dr. Gay performed the operation November 18th, in the same manner as upon the last patient, the wound being similarly dressed. The next day the patient said he felt better, having lost to a large degree his "nervous feelings" and headache. The wound progressed nicely, healing almost entirely by first intention.

November 27th, wound nearly healed and in good condition, there being no collection of fluid to produce any pressure upon the brain. In the afternoon patient had a slight fit, in which the tongue was bitten, and after which he was somewhat stupid.

December 2d, had another fit. Wound closed.

He was discharged, December 12th, in much the same condition as before the operation.

## IV. POPLITEAL ANEURISM; LIGATURE OF FEMORAL ARTERY; GANGRENE OF FOOT; AMPUTATION OF LEG; RECOVERY.

Frank H., thirty-six years old, colored, was admitted September 6th. Patient had been well up to three months ago when he began to notice pain in the left

knee and a swelling in the popliteal space. He continued to work as a porter in a family hotel until one week ago, when the pain had become so severe as to keep him awake at night and disable him from fulfilling his duties.

Examination showed a large swelling behind the knee, quite firm, yet slightly fluctuating, slight degree of pulsation with heart beat, painful, very sensitive on pressure. The tibial pulse was somewhat weakened and delayed. A bruit was heard over the tumor and for about two inches up the popliteal artery. Knee somewhat flexed, and only slight degree of motion. September 12th, patient went home to arrange some matters of business, and returned September 15th, for operation.

The following day he was etherized, and the femoral artery was tied at the apex of Scarpa's triangle with a double catgut ligature. Pulsation and bruit in the aneurism were entirely controlled. The edges of the wound were united with silk sutures, and a dressing of tr. benzoïn. co. was applied, after which the whole leg was thickly enveloped in cotton wadding, the cotton in its turn being covered with oiled paper. Patient was put immediately to bed, and the leg was surrounded by heaters and well covered in by the bedclothes.

Four days after operation the aneurism was notably smaller and softer, and gave rise to no pain. Sensation in the toes was somewhat lessened at first, but had then become nearly normal. The pad of compress cloth over the wound was wet with compound tincture of benzoïn three times a day.

September 23d the wound was found to have healed by first intention throughout a greater part of its extent, there being a little suppurative in the more superficial parts of the incision. Patient complains that the leg feels cold, though it is warm to the touch. Poultice applied to the wound.

October 6th there is some tenderness on dorsum of left foot, but no swelling of foot or leg. Two days later patient was allowed to sit up and to move about a little on crutches.

October 10th he insisted on going home to attend to important matters, and was discharged against advice, going out with crutches.

October 20th he was readmitted, on account of commencing gangrene of the left foot. A line of demarcation was beginning to appear just below the ankle, and the foot already exhaled an offensive odor. Dressed with charcoal poultice.

October 28th, the line of demarcation having formed below the ankle, the leg was amputated near the middle. The tissues seemed in good condition and well supplied with blood, though there was little hemorrhage from large vessels. After the operation the wound was doused with carbolic solution, and dressed with Lister gauze, to be changed daily.

For a week there was scarcely any discharge from the wound, the temperature remained at about 103° F., and the patient was slightly delirious. November 6th the discharge had increased and the flaps were beginning to slough, so that a few days later the dressing was changed to a charcoal poultice.

November 20th the slough entirely separated, leaving the end of the tibia exposed. Patient has become extremely emaciated, and has a large bed sore, though his general condition seems to be rather better than for some days past.

From this time he steadily improved till December

10th, when his temperature ran up to 103° F., and he began to complain of pain in the posterior part of the stump. On examination, a sensitive swelling was found which involved nearly the whole of the posterior aspect of the leg and extended a short distance above the popliteal space. A few days later, fluctuation having been distinctly felt, an incision was made by Dr. Cheever, who was then on duty, and this was followed by the discharge of a large amount of sanious pus, together with fragments of old blood clots. The flow was increased by pressure over the old aneurismal sac.

Convalescence from this date went on uninterruptedly, the bone being all covered in, the abscess contracting down to a small sinus, and the bed sore healing readily. He was discharged February 1st, with the stump healed, the knee flexed at a right angle, and a small sinus communicating with the old sac.

## Reports of Societies.

### QUARTERLY MEETING OF THE RHODE ISLAND MEDICAL SOCIETY.

A QUARTERLY meeting of the Rhode Island Medical Society was held in Providence, March 16th, the President, Dr. O'Leary, in the chair.

The following gentlemen were elected delegates to the St. Paul meeting of the American Medical Association: Drs. W. E. Anthony, G. P. Baker, Ariel Ballou, Otis Bullock, F. B. Carpenter, E. T. Caswell, J. H. Eldridge, G. W. Jenckes, Job Kenyon, Eugene Kingman, A. A. Mann, J. H. Morgan, G. A. Pike, and H. E. Turner. The President was authorized to complete the list and fill vacancies.

### EXPERT TESTIMONY.

DR. JOB KENYON, Chairman of the Committee on Expert Testimony, referred to the lack of interest among members of the Society as a contributing cause of the indifference of the General Assembly to the matter of expert testimony, and suggested that the Fellows sign a petition asking for such legislation as will mitigate the annoyances which medical witnesses now suffer. Later in the day such a petition was prepared and numerously signed by the Fellows.

DR. S. S. KEENE read the report of the Board of Censors and gave notice that he intended at the next meeting to move an amendment of the by-laws regulating admission to the Society, so that an examination before the Board will be necessary.

Drs. Gardner T. Swarts and Joseph N. Baratta, of Providence, were elected Fellows.

### CANCER OF OS UTERI WITH HYDRONEPHROSIS.

DR. LLOYD MORTON, of Pawtucket, reported a case of cancer of the os uteri with hydronephrosis. The patient was a stout American woman, aged sixty-two. During the past seventeen years she had frequently called on Dr. Morton to prescribe for what he termed the passage of biliary calculi. Twelve years ago she had an obscure steady dull pain in the right side extending to the groin.

In September, 1881, she complained of menorrhagia, and said it had existed at intervals since the previous March. The diagnosis of uterine cancer was not established until February, 1882. March 1st, she was seized with inflammation of the left kidney followed

by suppression of urine for forty-eight hours. There was then a slight secretion of urine for a few days and she died comatose March 9th. At the autopsy the gall-bladder was found filled with calculi. Two were quite large, an inch in diameter, but most of them were small. The left kidney was intensely inflamed.

Hydronephrosis of the right kidney; the sac containing eight ounces of serum, which had no urinous odor. A urinary calculus eight lines in length and three in width was impacted midway of the right ureter. This calculus probably passed from the kidney twelve years ago when she suffered pain in the right inguinal region.

An epithelioma of the cervix uteri involved the adjacent vaginal walls for about one inch.

#### SUCCESSFUL LITHOLAPAXY.

Dr. E. T. CASWELL reported a successful case of litholapaxy. The patient, who was sixty years of age, had suffered for six years from an enlarged prostate. The first operation was done in January last. Considerable time was spent in dislodging the stone, which was pocketed, and in an hour, sixty-two grains of phosphatic detritus were evacuated. Some tenesmus, but no chill followed this operation. The remainder of the stone, one hundred and seventy-four grains, was removed by a second operation a month later. No unfavorable symptom followed.

#### FIBROID TUMOR OF UTERUS.

Dr. Caswell also presented a fibroid tumor of the uterus weighing one and one half pounds, and measuring five and one half by three and one half inches, which he had lately removed with Thomas's spoon-saw. Hemorrhage was controlled by the prolonged hot douche. The patient, who was thirty-five years of age, did very well after the operation, and in seventeen days was ready to sit up, when chills developed and she died of septicæmia in three weeks after the operation. In a case like this, the tumor should be well drawn down before attempting enucleation.

Dr. WILLIAM H. PALMER, of Providence, next read a paper on

#### CRIMINAL RESPONSIBILITY,

of which the following is a synopsis:—

To define a standard of criminal responsibility has become an urgent need. The welfare of society being grounded upon the accountability of the individual, the importance of fixing the limits of that accountability is apparent.

In theory, every individual is assumed to be amenable to the laws under which he lives; lunatics and idiots alone being exempt as incapable of understanding their obligations. Practically, a large class of criminals is taking advantage of the unsettled opinions of scientific men concerning the distinction between depravity and disease to claim irresponsibility for their crimes. It is true that the prevalent pseudo-philanthropy concerning criminals, and the unscrupulous ingenuity of the lawyer who knows no person but his client, are alike influential in shielding the guilty from punishment, but the medical profession is responsible, to a still larger extent, for the numerous acquittals procured upon the ground of moral alienation.

Certain mental manifestations having been seen to be connected with certain organic conditions, it is advanced, on the part of the profession, that any pervers-

sion of conduct may be due to mental impairment, with an inevitable tendency to the conclusion that the patient, although perhaps a fit subject for sequestration, is not a subject for punishment.

The argument, however, that because certain diseases of the brain, nervous system, or body, produce mental states and actions similar to those of the insane suffering from general paralysis, mania, dementia, or any form of isolated mania, therefore all mania is the result of disease of the brain or body, cannot be sustained by demonstration, for there are many types of insanity which evince neither disease direct nor functional of the brain, nervous system, or body in life, nor does the post-mortem examination reveal any structural change, neurosis, inflammation, congestion, in a word, nothing abnormal.

The assumed mental impairment of criminals is by no means universally supported by facts; neither is an atypical brain construction always manifested by either abnormal conduct or perverted ideas. To predicate irresponsibility for crime upon a brain disease, which is not evinced by physical symptoms or pathological results, is to go faster than the facts of the case seem to warrant; to predicate irresponsibility upon an hereditary disposition to crime is to deny the obligation of the individual to self-control; and lastly, to predicate irresponsibility for crime upon a defective moral nature is to undermine the principles of human accountability, and to render the equity of penalty an open question.

Crime is not an evidence of insanity; neither does insanity imply irresponsibility. The knowledge of right and wrong is the sole admissible test of responsibility, and for this knowledge only a limited capacity is required. Every intelligence has a free agency and thereby capacity to do right. Inheritance and environment may stunt and impinge upon this freedom, but never absolutely destroy it. Selection and volition may, under the tyranny of organization, be difficult, but never quite impossible. In fact, so low a degree of mental development is required for comprehending one's obligation to the law, that it would be not only safe but scientific, to declare responsibility for all conscious acts of crime. In emphasizing the immunity from responsibility of the insane temperament, there is inculcated a sort of fatalism whose tendency, through example and the processes of heredity, is to lower the average will-power of the generation.

Guiteau, the miserable assassin of Garfield, is undoubtedly insane in the opinion of most alienists. It is indisputable that his mind and moral nature are disordered as evidenced by his supreme vanity and egotism, yet the forethought and deliberation with which he assured the success of his crime prove him capable of sound reasoning. Having willfully debased and enfeebled his own nature by indulging its worst and weakest propensities, he is none the less responsible for the crime which was the logical outcome of its debasement.

Punishment, as a deterrent to crime, is a therapeutic agent, the wisdom of whose employment cannot be disputed. The treatment of offenders which looks, first of all, toward controlling the spread of degeneracy, constitutes true philanthropy and correct pathology.

The President, in commenting on Dr. Palmer's paper, remarked that physicians are well adapted to refute the sympathetic and sentimental views that excuse crime under plea of insanity.

DR. F. B. FULLER, of Pawtucket, read a paper on  
MANUAL DILATATION OF THE OS UTERI AS A PART  
OF ARTIFICIAL DELIVERY.

Starting with the fact that in certain cases the immediate emptying of the uterus is desirable, the paper explained and defended manual dilatation as a new and comparatively untried method of accomplishing the most difficult part of the work.

The various operative procedures and mechanical dilators used to relax the os and induce labor require considerable time for their action, which renders them useless in many emergencies; when haste is not so necessary the inconvenience to both physician and patient of waiting is a serious defect.

Manual dilatation will be found efficient, comparatively easy of application, and quite safe for the patient.

DR. G. W. STANLEY, of Slatersville, tried this method successfully twenty years ago in a case of placenta previa. He approved of doing the operation early; never saw a serious result follow the practice.

#### TREATMENT OF PUERPERAL CONVULSIONS.

DR. GARVIN, of Lonsdale, reported a case of puerperal convulsions in a primiparous woman at the eighth month. The liquor amnii had escaped, but the os was undilated and there was no pain. Three quarters of a grain of morphia was given hypodermically, and an hour later half a grain more. Manual dilatation was begun at 5.30 p. m., and delivery accomplished in two hours. She had several slight convulsions during the night, but made a good recovery.

DR. GEORGE CAPRON read a brief paper on the Value of Venesection in the Treatment of Puerperal Convulsions. He thought it better to use small and repeated doses of morphia in these cases rather than the heroic doses recently recommended.

DR. ARIEL BALLOU reported five cases of puerperal convulsions occurring about the fifth month of pregnancy which were successfully treated by venesection and an opiate in medium dose.

DR. CASWELL called the attention of those who hesitate to use morphia boldly in treating puerperal eclampsia to the increasing number of these cases now reported in the medical journals, in which large doses of morphia have been used with brilliant results.

#### DEATH OF DR. DAVID KING.

The President announced the death of DR. DAVID KING, of Newport, and appointed Drs. C. W. Parsons, E. T. Caswell, and C. H. Fisher a committee to prepare resolutions attesting the esteem in which he was held by the profession.

The committee reported as follows:—

"Whereas, It has come to the knowledge of this Society that DAVID KING, M. D., long an eminent member of this Association, and an ex-President thereof, died at Newport, R. I., on March 7, 1882; therefore,

"Resolved, That in the decease of DR. KING the Rhode Island Medical Society has lost one of its most respected and honored associates, a physician of large culture and rare judgment, and a gentleman of the utmost urbanity and courtesy of manner.

"Resolved, That his connection with various literary, historical, and scientific organizations has reflected credit on the Society and the profession of medicine.

"Resolved, That the above resolutions be communicated to the family of the deceased, with the expression of our sympathy."

#### PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

APRIL 10, 1882. DR. J. C. WARREN presided.

#### POPLITEAL ANEURISM.

DR. C. B. PORTER reported some cases of Popliteal Aneurism.<sup>1</sup>

In answer to a question by Dr. Gay, DR. PORTER said that he preferred the treatment by compression to tying the vessels, because in this way a surgical operation, which is always a dangerous procedure, is avoided.

DR. GAY said that one case had been cured at the City Hospital by flexion, but that it was impossible to give in this method of treatment sufficient opium to control the pain. He had himself treated two cases by the catgut ligature. The first case recovered with a tumor in the popliteal space, but no pulsation there nor in the tibial artery; this patient was afterwards admitted to the hospital for rheumatism, and the popliteal spaces were then found alike, though there was still no pulsation in the tibial artery.

In the second case, where there was a large tumor in the left popliteal space but no pulsation, and at first no bruit, he operated on it in the same way; the case did well, but contrary to advice left the hospital at the end of six weeks, and returned ten days later with great pain and two thirds of the foot gangrenous, so that the foot had to be amputated, and the patient was afterwards discharged with a slight fistula in the calf.

In answer to a question by Dr. Homans, DR. PORTER said that there was less danger from gangrene of the parts below where compression was used, as the process was slow, and collateral circulation could thus be established more easily.

DR. WARREN said that the old operation of laying open the vessel and tying both ends was usually advised for false or traumatic aneurism, and not for true aneurism. He had treated two of these cases of traumatic aneurism, one in the popliteal and one in the femoral space; they were both of long standing.

The popliteal aneurism, which more than filled the whole space, had been caused by a bullet in 1865; he operated on it in 1875, after several twelve-hour attempts at compression under ether had failed, the pulsation ceasing for a time but then returning. Phlegmonous erysipelas set in, and sudden death occurred from hæmorrhage from the femoral artery.

In the second case the aneurism was as large as a child's head, and was varicose; the same operation was performed, and the case has done well.

DR. C. J. BLAKE showed a tubular share for the removal of polypi, a description of which will appear in the next number of the *American Journal of Otolaryngology*.

#### DIAGNOSIS OF FRACTURE.

DR. FIFEELD spoke of the difficulty of diagnosing those cases of fracture where there was neither shortening, deformity by measure, or anything notice-

<sup>1</sup> See page 361 of this number of the JOURNAL.

able. In these cases an ecchymosis which amounts to a large effusion is of great value as pointing towards a fracture and not merely a sprain. He cited a case in support of this view, where at the time of the injury nothing could be found, on account of the great swelling and effusion, until three weeks later, when a marked fracture was discovered.

#### LACERATION OF CERVIX UTERI IN ABORTION.

DR. C. M. GREEN reported a case which was of interest in its bearing on the aetiology of laceration of the cervix uteri. The patient was about three and a half months advanced in her first pregnancy, and when first seen had been suffering with severe uterine pains for an hour. Examination revealed the os to be dilated to half an inch in diameter and the membranes to be protruding. Morphine was given to the extent of preventing sensibility of the pains, but the uterine contractions continued, and the fœtus was expelled one hour later. Examination of the cervix disclosed a bilateral laceration; it was found, too, that the pericævium had been torn from the occiput of the fœtal head, showing that it must have encountered much resistance in its passage through the cervix.

The case, therefore, afforded a fresh illustration of the now well-recognized fact that abortion is very often attended with laceration of the cervix, especially when the labor is rapid; the liability to rupture being greatly enhanced by the fact that the cervix in the early months has not undergone sufficient softening for rapid dilatation.

### Recent Literature.

*A Treatise on Human Physiology, designed for the Use of Students and Practitioners of Medicine.* By JOHN C. DALTON, M. D. Seventh Edition. Philadelphia: Henry C. Lea's Sons & Co. 1882.

The handsomely printed and luxuriously bound new edition of this well-known book presents ample evidence of the author's wish to keep abreast of the times. The six years that have intervened since the previous edition have been fruitful in research and have brought most important additions to the stock of physiological text books. The book before us unfortunately fails to hold its own in the struggle for existence, and demonstrates again the difficulty of putting new wine into old bottles. The text and illustrations have undergone much modification and curtailment, without exception, we believe, to the benefit of the reader.

The old charm of style is retained and will doubtless continue to prove attractive to many who would shrink from a better book. This is to our mind a great objection, for it involves an immense amount of diffuse writing to arrive after all at incomplete conclusions which might have been stated in one fourth the space to the great advantage of the student. When we consider the importance that practical experimental physiology has attained, the complexity of its methods, the bearing that its researches have upon all other fields of medical work, we must recognize the necessity of conveying some knowledge of all this in each and every text book for medical "students and practitioners." We believe that we are justified in saying that a knowledge of experimental physiology must be the very cornerstone of modern medical training, if good practitioners are to be formed, — men who shall have a just apprecia-

tion of the work of their fellows, who shall have a scientific interest in medicine (the only thing that can save us from the degradation of being mere *routiniers*) and be capable of resisting the dangers of specialization. *Post hoc ergo propter hoc* is the fundamental error of nine medical men in ten, and it is the peculiar province of physiology to convey that appreciation of methods and their limitations — training in practical logic, that is — whose lack no clinical instruction can possibly remedy, or the courses of the various "ists" supply. We cannot but feel that the effort to write books down to the level of students who are, we hope, below the average, must always be harmful; a good text book ought to be above the heads of the many, and to suggest and encourage the desire to know more. It is the work of the teacher and the lecturer to dilute and explain; books meant to be popular (in no obnoxious sense) ought to be small. We should suggest then that a judicious use of foot-notes and varieties of type would render it easy to separate the indispensable and well established from that which is less necessary or theoretical, but it is a misfortune for any medical student to be encouraged to underrate the value of theoretical conclusions.

We have said that the author shows an earnest desire to keep abreast of the times. His account of the visual purple, of the vasomotor nerves, of localization in the brain, gives ample evidence of his intentions, not to mention marked traces of the same effort in other departments.

But we miss everywhere satisfactory evidence that the author has a true modern point of view. Physiologists are no longer content to be merely descriptive, they are striving at every point to generalize, and rightly too. For example, the study of secretion has thrown much light upon the action of the glands, upon the influence of the nerves, and the functional changes of the cells themselves. Of these results, which are assuming a very general character, the student gets a very insufficient knowledge — or rather he gets complete ignorance — and has to be satisfied with the bald statement that the gland A furnishes a certain secretion B, whose general properties are C and D.

Modern physiology recognizes more and more the function of the cell as the element of life, but the reader of Dalton will almost look in vain for the word, except in purely anatomical relations. The absence of this general standpoint is sadly felt in that section of the book devoted to physiological chemistry, which includes a very incomplete enumeration of some of the substances found in the human body and of some of their properties. Fortunately the author has succeeded in reducing his use of "proximate principles" to a minimum, and we hope another edition will witness the disappearance of that and "matters" too.

As to details of criticism we will try to be brief, although many points have suggested themselves during an examination of the book.

The classification of the chemical ingredients of the body (page 33) is unsatisfactory; that the "crystallizable nitrogenous matters" should constitute one class and the "coloring matters" (all of which, by the way, are nitrogenous and crystallizable) another, has no chemical justification. In the list of inorganic substances (page 35) we miss (besides such trifles as oxygen, nitrogen, and carbonic acid) sulphuretted hydrogen and ammonia, whose presence is certainly less accidental than that of lead.

The transformation of starch into sugar no longer permits of such simplicity of statement as on page 53, for chemists distinguish at least two dextrines besides declaring the sugar to be maltose and not dextrose. The good tests for sugar deserve fuller enumeration; the account of Trommer's test is unsatisfactory and partially false. The description of alcoholic fermentation is incomplete, and we miss any account of beverages as a part of food; indeed, we may remark in passing, that the worship of Bacchus, as well as that of Venus, hardly has justice done it — we mean physiological justice, of course.

Glycogen is a more important ingredient of the muscles than the student would infer from page 60; indeed, if we may venture to draw conclusions from Boelhm's determinations for the cat, at least one half of the glycogen of the body is to be found in the muscles! The account of albuminoid bodies does not compare favorably with that to which other writers have accustomed us. Coagulation is only partially explained, and it is not true that this change is not produced by organic acids, for the proper amount of acetic acid added to alkaline albuminous urine, for example, causes a beautiful coagulation. The connection of albuminoid substances with "catalyses" (page 76) is no more peculiar to them than to alcohol, which, under the influence of sulphuric acid and heat, undergoes a "catalytic transformation" into ether.

The description of ferments (page 85) is generally good, but we miss a sufficiently full explanation of the best methods of obtaining them by extraction of the various organs for digestive purposes, a topic of growing importance, and particularly valuable to the numerous pepsinophiles.

The allusion to the importance of iron for the plant, on page 97, should be compared with the superfluous account of chlorophyll on page 103, where almost the opposite is stated, and correctly too. On page 110 we should have liked to see mention of Strassburger's convenient modification of Pettenkofer's test for the biliary salts. The relations of urea (page 116 and again on page 328) and the general question of the excretion of nitrogen are not adequately discussed, and it should not be forgotten that the hypobromite method determines the nitrogen and not the urea. Very many most important chemical substances are not mentioned at all, and we miss particularly our old friend sarcolactic acid, to which, perhaps, more virtues and vices have been attributed than to any one substance of the animal body.

Foods are discussed in Chapter VII, in a fairly lucid manner, but the explanation of the action of cooking is inadequate. The absence of the sulphydryl in saliva is more frequent than Dalton admits. It should be remembered that acetic acid also gives a red color with ferric salts. The influence of the nerves on salivary secretion is barely touched upon on page 476. The account of the bile is good. The researches of Eichhorst on the work of the intestines seem to have been overlooked, and the absorptive capabilities of the large intestine deserved attention, in view of the recognized importance of rectal alimentation.

The chapter on respiration, otherwise good, would be excellent did the author but realize it is in the cell, physiologically speaking, that we live, move, and have our being. It ought not to be overlooked, too (page 257), that the blood is as much a tissue as the muscles are. There is no mention of Garland's

recent interesting researches on pharyngeal respiration.

The description of perspiration is not up to the times. The past few years have given this process a dignity barely suspected before, and it is now to be ranked among the true secretions, attributable to cell activity, amenable to nervous influences, and independent of the blood, as the curious experiments of Luchsinger and Miss Kendall have shown. In another organ — the kidney — the phenomena of secretion have of late been made much clearer, at least topographically, but there is no mention of these interesting researches in the book before us. It is, by the way, by no means certain that the albuminous urine of pregnancy is occasioned by pressure on the renal veins (page 335).

In the chapter on the circulation we miss mention of the negative pressure in the veins, and the account of the rate of the blood-flow is perhaps too dogmatic. There is good reason to believe the time required for the complete circuit of the vascular system to be nearer twenty-five than twenty seconds.

Not to be too prolix or too captious, we will only say, in reference to the chapters on the nervous system, that the evidence for a difference in the rate of transmission in sensory and motor nerves is not satisfactory; that a fuller account of what is known as the reaction time (and particularly of the influence of practice), and of what we may perhaps designate as the inherent laziness of our nervous terminal apparatus (page 513), is desirable.

We have failed to find any account of a phenomenon which occupies about one third of our extra-uterine existence, — sleep, — and if his twin brother, — death, — is alluded to it has escaped us. As in the former edition, the spleen is neglected. We know, to be sure, but little about this organ, but the student ought to be told that little in order to be protected against false theorizing, whose occurrence is usually inversely proportional to knowledge. There is, too, no mention of tendon reflexes nor of vomiting, and the thoughtful student, if he have read so far, will wonder why a child needs to be born at all.

The index is very full, and, like the entire book, wonderfully free from typographical errors. We miss, however, Chyme (a word, by the way, we should like to see retained), Birth, Fœtus.

*Analytisches Hilfsbuch für die physiologisch-chemischen Übungen.* By DR. TH. WEYL. Berlin: Springer. 1882. Pages 32.

In a convenient little series of tables Dr. Weyl, of the University of Erlangen, has presented a concise view of the steps to be taken in those analyses which concern the medical student and some practitioners. All interested in such work will find this book useful in learning, and to refresh the memory or for practical instruction in the laboratory, but it is, of course, only a helpmeet, and does not profess to take the place of the larger text books.

— Professor Klebs has accepted the appointment to a professorship at Zurich, and will lecture there during the coming summer. A new pathological institute has lately been built there.

# Medical and Surgical Journal.

THURSDAY, APRIL 20, 1882.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year including postage.*

*All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.* HOUGHTON, MIFFLIN AND COMPANY,

NO. 4 PARK STREET, BOSTON, MASS.

## THE ANTHROPOMETRIC LABORATORY.

FRANCIS GALTON, F. R. S., writes an article in the *Fortnightly Review* for March, suggesting that persons should be encouraged by their physicians, if need be, to have themselves and their children accurately appraised, that a few scientific men who have the special knowledge required for the purpose should endeavor to systematize the methods by which this could best be done, and that thus anthropometric and medical facts might be recorded by the side of photographic chronicles maintained from childhood to age, and that access to such records would be of the utmost value to families and physicians in guarding against evil or profiting by favorable tendencies, an easy recognition or anticipation of both being thus readily secured.

Mr. Galton holds a belief, based upon some observations upon children of the same parents, and especially upon twins, that the possibilities of a child's future career are more narrowly limited than, as he says, our forefathers were fondly disposed to believe. Such a belief we should call old-fashioned, for certainly in the United States the great majority of moderately educated young people flatter themselves that there is almost nothing which a *smart* American cannot accomplish, if he only wants to badly enough, and few stations which he may not fit himself to fill, at least with considerable personal satisfaction, and in this generous estimate of the scope of free-will there are some women, certainly at the moment, who outdo the most sanguine men.

However, be this as it may, we ourselves are inclined to agree upon this point with Mr. Galton, and accepting such a belief we readily agree with him also that "it is highly desirable to give more attention than has been customary hitherto to investigate and define the capacities of each individual. They form his stock-in-trade, the amount of which admits of definition, whereby he has to gain his livelihood, and to fulfill the claims upon him as head of a family and as a citizen. So far as we succeed in measuring them so far almost in an equal degree should we be able to forecast what the man is really fit for, and what he may undertake with the least risk of disappointment. They would encourage him if unduly timid, or they would warn him from efforts doomed to be wasted."

Among the details of bodily form and faculties which can, or apparently could be, measured with some precision are instanced, besides the common ones of height, weight, chest-girth, capacity of lungs, color of

hair and eyes, — energy, strength, agility, the coördination of muscles and eye, sense, discrimination, persistence of impressions, memory, time lost in forming a simple judgment.

Personal data in respect to intellectual and emotional capacities and to special aptitudes and tastes would be more difficult to acquire and are not touched upon. Then the data for the medical history of a man's life from the observations made by his physician in his successive illnesses would form still another department — a medico-metric. To such a laboratory it is suggested that physicians might send patients to be tested in any way they wished, as physicians send their delicate instruments to Kew Observatory to have their errors ascertained.

The motives which might induce a person to take the trouble of getting himself accurately measured and appraised from time to time and of having the results recorded are thought by the writer to be: (1) their biographical interest to the person himself, to his family, and descendants; (2) their utility, especially in a medical point of view, to himself in after life; (3) the information they might give of hereditary dangers and vital probabilities to his descendants; (4) their value as future materials for much-needed investigations into the statistics of life-histories.

Some of Mr. Galton's suggestions are certainly of value, but we fear men and women must show less desire for embellished portraits and become either much more altruistic or more scientifically selfish before these gain practical and successful realization.

## PAROXYSMAL HÆMOGLOBINURIA (*A Frigore*).

UNDER the title of *A New Form of Hæmoglobinuria* in *Man*, Dr. R. Fleischer<sup>1</sup> gives curious and instructive details of a case occurring in a German soldier who was under careful and prolonged observation at the hospital at Erlangen. The case differs in many particulars from any we have seen reported. The appearance in the urine of the coloring matter of the blood either persistently or at intervals has hitherto been referred to the action of poisonous substances (hæmoglobinuria toxica), to exposure to cold (hæmoglobinuria a frigore), or from coincidence, and, in absence of a better explanation, to the influence of the malarial and syphilitic poisons. The action of certain chemical substances in disorganizing the blood and setting free the coloring matter is well known, and need not be more than referred to in this connection. Nor need we concern ourselves with similar results occurring occasionally in the course of acute affections, nor with the secondary or false hæmoglobinurias, which are, more properly speaking, hæmaturias, resulting from chronic renal disease, or from an abundance of oxalates in the bladder.

The true *paroxysmal* hæmoglobinuria, as originally described by Drs. Harley and Dickinson,<sup>2</sup> under the name of intermittent hæmaturia, is characterized by a bloody-colored, albuminous urine, entirely free from

<sup>1</sup> Berlin. Klin. Wochenschr., No. 47, 1881.

<sup>2</sup> Med.-Chirurg. Soc. Trans., lxxviii., 1864.

blood globules the periodic liberation of the red coloring matter taking place most probably within the blood course, and not being dependent upon the introduction of any specific poison. Ætiologically the attacks have so frequently been observed as a sequence to exposure to cold that the terms *hibernal* or *a frigore* have been proposed as more appropriate than the prefix paroxysmal. Mesnet, who lately reported a case under his care in the Hôpital Sainte-Antoine in which the attacks could be produced at will by exposure to cold for even so short a time as fifteen minutes,<sup>1</sup> goes so far as to state, in a memoir presented to the French Academy of Medicine,<sup>2</sup> that the essential characteristic of paroxysmal hæmoglobinuria is that it recurs in attacks at longer or shorter intervals under the influence of a constant cause, cold. He further considers the cause and effect as parallel, the rapidity and intensity of an attack being almost always proportioned to the more or less energetic action of the cold. Dreyfus-Brisac,<sup>3</sup> reviewing the subject, follows the same general opinion.

Fleischer's case, referred to above, while answering all the requirements of a strict diagnosis, and being under careful supervision, differs from Mesnet's and others previously reported in that the attacks, though equally with those in Mesnet's patient producible at will, were shown to be in no way dependent upon or brought on by exposure to cold. The attacks were always preceded by and always followed one immediate cause, walking exercise. Other forms of exercise, though more active and laborious, did not produce the attacks. The patient's general condition and appearance were but little affected, nor was the passage of bloody urine accompanied by any elevation of pulse or temperature or any derangement of any internal organs. The serum of a blister formed during an attack presented under the microscope the hæmoglobin as found in the urine. From the absence of morphological elements from the urine, as shown by microscopical examination, the absence of pain in the region of the kidneys, the simultaneous appearance and disappearance of albumen and hæmoglobin, the presence of hæmoglobin both in the urine and the serum, Dr. Fleischer is led to predicate that hæmoglobinuria is a pure, primary affection of the blood.

#### BOSTON SEA-SHORE HOME.

THE directors and officers of the Boston Sea-Shore Home are already preparing for their good work for the approaching summer. Last summer the house at Winthrop was opened July 7th and closed September 13th. There were 149 patients, of whom 44 were adults and 105 children. Some enlargement and changes in the building are contemplated, but the directors do not wish to enlarge the institution so far as to change the home character which it has had from the beginning. They urge again upon the city government, upon the Board of Health, and all who are interested in preserving the lives of our people, that another home, if

not larger, would probably be fully occupied every summer. At a very small charge to the city it would preserve the life of one or two hundred children of the very poor, who in the close streets and oppressive heat of summer will certainly die without such relief. On several islands, and on the mainland at Winthrop, the city owns land which could be used for such a purpose. A proper building, fitted for use in summer, and not to be occupied in winter, could be built for twenty-five hundred dollars. Their experience shows that two hundred or more patients can be maintained, each for an average of about a week, at the charge of sixteen hundred dollars a year.

"We can conceive," they say, "of no expenditure so small which would do so much to improve the bad death-rate of the city. The average mortality of children under five years old, in the three summer months for the last six years in the city of Boston, has been 1176. The present population is estimated at 397,628. These are the years of the work of the Society. The average mortality of the preceding five years was 1202, with an average population of 290,216. The mortality in 1881 was 1132; this is even below the average of the six favorable years. The annual number of deaths of children is less in the latter period than it was in the former, though the population has increased twenty per cent.; this is a gratifying result. The directors believe that any system which will enable physicians among the poor more frequently to give to sick children the tonic of a sudden change of air will diminish still further the mortality of the summer months, which is still largely in excess of what could be desired. It will be observed that the terrible mortality which such figures indicate belongs only to the honest classes of our people."

#### THE BACILLUS OF TUBERCULOSIS.

THE *Allgemeine Medicinische Central Zeitung* and the *Berliner Klinische Wochenschrift* for April 1st contain a brief reference to the discovery by Dr. Robert Koch of the bacillus of tuberculosis. This he has succeeded in cultivating through six or eight generations without diminishing its power. The bacillus, as far as has yet been proved, is identical both in men and animals. By inoculation, as well as by injection into the vessels, Koch has succeeded in producing acute miliary tuberculosis as well as cheesy processes in animals otherwise free from tuberculosis. This small bacillus grows very slowly, and is essentially different from all the other pathogenic bacteria and micrococci. The full text of the paper is promised for an early date.

Koch does not usually herald his discoveries until they are pretty well proved. Moreover, his late onslaught upon Gravitv for rushing in unseemly haste to unwarranted conclusions in regard to the inoculation of fungi furnishes an additional guaranty, if such be needed, that he is not likely to choose the present moment himself for abandoning those habits of exact method and care which have, as a rule, characterized his work hitherto. Our readers are likely to hear of this discovery again.

## MEDICAL NOTES.

— Mr. Barrand, of Gloucester Place, has just completed his great portrait picture commemorative of the International Congress of 1881. This remarkable effort of photographic portraiture includes in one picture six hundred and eighty-four portraits of members of the Congress. The portraits are all taken from life, and were taken specially for this purpose. The popular size of the picture is twenty-nine by twenty inches, and an extra size forty-seven by thirty inches; thus some idea may be formed of the importance and interest; and this is the most remarkable collection of portraits which has, we believe, ever been brought together in one plate. The work has been executed with very great skill and success. There is not one portrait among the many hundreds of persons whom we can recognize that may not be pronounced a good likeness, and some of the portraits are certainly strikingly good; especially may be noticed for their life-like character the portraits of Owen, Spence, Struthers, Charcot, Savory, Bucknill, Lister, Donders, Hebra, Andrew Clark, Billings, Virchow, Sir W. MacCormac, Bigelow, Esmarch, Langenbeck, Sir James Paget, Sir George Burrows, Sayre, Spencer Wells, Grainger Stewart, Sir William Muir, John Simon, Sir Henry Thompson, and Austin Flint. We have no doubt that a very large proportion of the members of the profession will be tempted to possess themselves of this interesting commemorative picture. — *British Medical Journal*.

— The Secretary of the Connecticut Board of Health reports for February that malarial fevers begin to show renewed activity, and also their allied disorders. Dumb ague is stated as very common in Plainville, and malarial neuralgia. No pronounced chills. A fatal case of congestive chill in an old man is reported from Oxford, and with one death from pneumonia constituted the mortality of the place. Several cases and one death from typho-malarial fever are reported from South Manchester. Bloomfield, New Canaan, North Manchester, Watertown, Simsbury and several other towns report cases as already appearing.

In the registrar's report from Groton several deaths were attributed to typho-malarial fever, and if originating there, this town must be included also in the malarial zone, which is extending towards Rhode Island.

The unusual fatality from typhoid fever is a noticeable feature in the table, especially since the disease has been so infrequent in this State of late years, although 1881 was not such a year, however. Cases are reported from Avon, New Canaan, one fatal case from Williamantic, and quite frequently from different parts of the State, usually where malarial diseases are decreasing in frequency.

— Mr. E. Ray Laneaster, M. A., F. R. S., has been appointed to the chair of Natural History in the University of Edinburgh, as successor to Sir Wyville Thompson, LL.D., whose death was lately announced. Sir Wyville Thompson will be remembered in connection with the expedition of the Challenger.

## NEW YORK.

— At the last meeting of the Academy of Medicine the paper of the evening was by Dr. Fessenden N. Otis, who presented in detail with pathological specimens a case of persistently recurring spasm of the bladder resulting in thickening of its walls, dilatation of the ureters and hydronephrosis, and followed by death from uræmia.

— Dr. George M. Beard recently read before the New York Academy of Sciences a paper entitled, *Psychological Explanation of the Salem Witchcraft Excitement*, and the Practical Lessons derived Therefrom.

— The Medico-Legal Society has lately given attention to the consideration of needed changes in the statutes of New York State relating to the office and functions of coroner. The subject was referred to a committee of Messrs. Orlando C. Calvin and Austin Abbott, and Drs. Alexander B. Mott, Charles A. Doremus, George M. Beard, and Webster Beach, and this committee has submitted a unanimous report, which has been ordered to be printed. The report says that the committee are substantially agreed in the opinion that the principal changes needed are the abolition of the coroner's jury, and the substitution therefor of an intelligent and thorough medical examination.

— Six cases of probable trichinosis in one family are reported from Brooklyn, trichinae having been found in the remaining portions of a ham of which they had all partaken.

— During the past week, Richard C. Flower, a quack physician of Fifth Avenue, was indicted on complaint of Dr. Frederick R. Sturgis, president of the County Medical Society, for practicing medicine without proper qualifications, and pleaded guilty when arraigned in court. He was fined two hundred dollars.

— Of \$141,000 excise funds just appropriated by the Board of Apportionment, \$44,969 is to be distributed among the various medical charities of the city. Of these institutions St. Francis Hospital gets the largest amount, \$6300, and the Yorkville Homœopathic Dispensary the smallest, \$177.

— On the same day on which Jumbo arrived, there came to this port from Europe a Chinese giant, who seems to hold the same relative position among other giants that Jumbo does among elephants. His name is Chong Chi Lang, and he was born in Pekin thirty-five years ago, but of late years has been on exhibition in the various cities of Europe. He is nearly eight feet and a half high, and weighs more than five hundred pounds. He is accompanied by his wife who is five feet in height, and has feet measuring only three inches in length.

## CHICAGO.

*College Changes.* — There has been of late an extensive upturning in the faculties of the colleges. The Faculty of the Chicago Medical College has lost by resignation Dr. Roswell Park, Demonstrator of Anatomy; Dr. R. L. Rea, Professor of Anatomy. The

former becomes Lecturer on Surgery in Rush College; the latter Professor of Surgery in the new College of Physicians and Surgeons. Dr. John E. Owens leaves a professorship of Orthopedic Surgery in Rush to assume the Chair of Operations of Surgery and Surgical Anatomy in Chicago College. Dr. F. L. Wadsworth has resigned the position of Adjunct Professor of Physiology in Rush, and Dr. W. T. Bel-field has been appointed Lecturer on Physiology in the same institution. Dr. J. H. Long becomes the Professor of General Chemistry in Chicago College; Dr. A. G. Pain becomes Lecturer on Dermatology; and Dr. O. C. DeWolfe, the Commissioner of Health of Chicago, becomes Professor of State Medicine and Public Hygiene, in this College, — the last two are new positions in this school.

On the 28th ultimo, the Chicago Medical College, medical department of the Northwestern University, held its commencement and graduated a class of thirty-seven.

#### MORTUARY.

Within a few weeks the profession has lost by death four most excellent practitioners and much respected men.

*Dr. Alexander Fisher* had attained an advanced age. He had practiced in Chicago for more than a quarter of a century; he was one of the founders of the Woman's Hospital Medical College, and for several years was one of the professors of surgery. He was fortunate in enjoying the respect and esteem of the whole profession, and he was esteemed both for his sterling qualities as a citizen and for his high character as a practitioner. He had not been in active practice for the last few years.

*Dr. Daniel S. Root* was at the time of his death little over forty years of age. Graduating in Rush College in 1867, he served as an interne in Cook County Hospital a year and a half, when he settled in practice in this city. He acquired a large practice and was very successful. One of the quietest of men, he was known thoroughly by but few of our city physicians, but those who knew him prized his acquaintance and friendship deeply. Few but his intimate friends knew it, but he was one of the best students of general science in the local profession. Botany was a favorite study, and he left a large and valuable herbarium.

*Dr. Cass Mason Dodge* was a comparatively young man, and in his death another victim is added to the list of physicians who have died of diphtheria contracted from patients. The evidence of this origin of his disease is said to be indubitable. He had practiced less than ten years, but had established a good reputation as a practitioner and was respected as a man.

*Dr. James Allen Mead* had been a druggist for many years when he studied medicine and graduated in Rush College in 1876. He opened an office over his former store, and such was the grace of his nature and his professional industry that he soon became a busy practitioner indeed. His was a nature men found it impossible to dislike, — his acquaintances were his friends.

#### Miscellany.

##### THE SANITARY STATE OF PANAMA AND THE INTEROCEANIC CANAL MEDICAL SERVICE.

MR. EDITOR, — In view of the present delicate diplomatic relations of our country in regard to the control of all interoceanic communication across the Isthmus of Darien, and the possible complications in the future, as well as in the interests of public health and commerce, a few remarks upon things isthmian may prove acceptable to the readers of the JOURNAL.

Approaching Panama by steamer from the south, on a bright day, one is struck with the old-world beauty, picturesqueness, and even grandeur which the city presents, as it sits upon rising ground, inclosed by old bastions nearly hidden by luxuriant, bright-flowering creepers, over which are seen moss-covered towers and red-tiled roofs, the whole being softly outlined against the hazy blue and green of Mount Ancon, a lovely tropical hill, rising five hundred and forty feet, a mile to the westward. But the glamour, which at a distance has awakened one's poetical fancies, is rudely dispelled as, nearing the city, the boat passes under its bastion walls, and the old, tumble-down, disintegrating buildings, reeking with stench in the merciless torrid sun, present themselves in all their squalid badness.

Panama is built upon a peninsula sufficiently elevated to insure perfect drainage, assisted as it is by a rise and fall of the tide of from eighteen to twenty-two feet; but the city is built in the true Spanish style, narrow streets with no sewers, so that the only drainage is surface, and all refuse is thrown into the streets, to lie there and putrefy till washed into the bay by heavy rains. The general unhealthfulness of the city is due chiefly, I think, to defective drainage, overcrowding, and household and personal uncleanness. The squalid portion of the place, which is practically two thirds of it, is miserably constructed; the houses are one and two-story tenements, with the first floor invariably of mother earth, and each room generally sheltering in vice and filth an entire family. As one walks through the narrow alleys it is necessary to pick each step to avoid stagnant pools of water, kitchen slops, and household refuse of every character, the air being disgustingly, if not dangerously, odorous at each turn. Had Coleridge known Panama, Cologne would have been robbed of one of its chiefest claims to immortalization.

Of course, the climate of the isthmus is bad, and thoroughly so in the line between Panama and Aspinwall; but the high, solid foundation of the former city, and its proximity to the bland Pacific, makes it naturally more salubrious than the low-lying, swampy locality of the latter. The rainy season sets in about the middle of May, and continues till November, during which time the country is literally drenched, and a healthier state obtains, owing to the vigorous surface drainage. The dry season is only comparative, for it is rare that a day passes at any period without some rainfall. The geographical position of the isthmus, the break here in the Cordilleras, the vast, impenetrable forests, and the almost total absence of cultivated land, naturally produce a hot, humid, devitalizing climate, altogether at variance with the health of man. From such a pregnant nidus one is not surprised that malarial manifestations are abundant, or that the most general types, intermittent and remittent fevers, attack

every one almost without exception. These fevers are much more virulent at the change of the seasons, when the mortality is indeed alarming.

All desperate fevers are here called *fiebra perniciosa*, and under this head the Panaminians, one and all, professional and non-professional, endeavor to conceal the terrible *fiebra anarilla*, which has now taken a permanent residence in the germinating squalor of the city slums. The first appearance of yellow fever in Panama is said to have been in 1859, and was confined to the Morro of Taboga in the bay. In 1868 it again visited the port, decimating the crew of the United States Steamship Jamestown, since which time it may truly be said to have never left the isthmus.

I visited the harbor two years ago in the United States Steamship Lackawanna, and it being known that yellow fever prevailed on shore, the United States consul was asked to give definite information in regard to it, which he did by denying its presence *in toto*. Feeling certain, however, of the falsity of the assurances given, Surgeon C. H. White, United States Navy, called on the native profession, and from Dr. Amador, the ablest man in the place, ascertained that yellow fever existed in epidemic form, and, moreover, that the large moneyed corporations suppressed information concerning it through every possible channel. Again visiting this place two months ago, I was fortunate enough to get reliable information from a practicing physician, Dr. Nelson, to the effect that yellow fever was now recognized as endemic in Panama and Aspinwall, and also in that part of the isthmus immediately connecting them. Two deaths occurred from it during our stay of twelve days, one happening to be aboard of a ship anchored near us.

Until December last a regular board of health had never been organized on the isthmus, owing to the strong opposition of corporations and commercial men in general; but finally, the president of the state of Panama, recognizing an urgent necessity, has constituted a board of health and quarantine, with Dr. Hurtado, a graduate of Cartagena, president; Dr. Nouel, a graduate of Bellevue Hospital Medical College, vice-president; Dr. Miranda, a graduate of Cartagena, secretary; and Dr. Nelson, a graduate of Bishop's College, Montreal, health and quarantine officer *pro tem*. These gentlemen have a stupendous task before them, and brilliant results are not to be expected in a hurry; but they seem in earnest, and it is to be hoped that whatever they do will be put upon record for the benefit of future seekers after information, as well as for their own glorification.

One who has not traveled through Spanish America can form no idea of the happy-go-lucky, indifferent, and general slipshod state of government. Records are seldom kept, and when they are, cannot be relied upon. After vainly seeking mortality statistics from physicians and public officials, I paid a visit to the various cemeteries, and by overhauling burial books and questioning the keepers, ascertained that the Catholic (native) interments amount to one hundred monthly, and the foreign to ten, giving an annual death-rate of eighty-eight per one thousand. Of these deaths at least one half are due to malarial (yellow?) fevers, one fourth to small-pox, and the remainder to pulmonary and intestinal diseases, syphilis, accidents, etc., etc. I carefully inspected the cemeteries, and cannot pass on without remarking upon the largest one, the immediate property of the bishop. It was built by the

Spanish government nearly two hundred years ago upon a boggy piece of land, a mile to the westward of the city. It consists of three hundred and sixty-five niches arranged in three tiers, forming a hollow square. Only the wealthy can indulge in this ultimate luxury, and upon the demise of one of these favored sons of fortune the body is deposited in one of the niches, sealed up by a suitably engraved tablet, to remain so long as cadaveric rent is paid to the church; but let the defunct's relatives fail to satisfy its rapacious demands, and soon the remains in its coffin is tossed into the swamp, just to the rear of the cemetery, where at all times may be seen the unsightly remnant of ancient and recent dead, old Spanish bidaños, proud doñas, fair señoritas, and new-born babes lying in a promiscuous heap of putrescence ten feet high, their white, staring, tongueless skulls mutely protesting against such barbaric desecration of the dead. My nerves are well tempered, but I confess this sight filled me with uncontrollable disgust and repugnance. Such a constant source of disease germination and dissemination within a mile of the city, of course, must contribute greatly to its unhealthfulness. Will the new health authorities dare interfere with this right of the church? I think not.

The city affords two small, poorly constructed hospitals, so thoroughly had in every way as to merit only a sweeping condemnation.

Upon the incorporation of the Panama Canal Company by M. de Lesseps, his particular friend, Dr. Louis Campayo, was called upon to draft a plan for the organization of a general sanitary service in connection with it, to which he responded by a most elaborate projection. Dr. Campayo is a man of undoubted ability and learning, who is at the same time gifted with a happy fluency in the expression of his knowledge; the cosmical advantages he has enjoyed for so many years, especially his former relations with the Suez Canal, peculiarly capacitate him for such an undertaking, but few men are endowed with universal capacity, and the weak point of this chief of the medical service would appear to be a want of executive ability. After having so admirably drafted his sanitary project he seems quite unable to execute it. A year has already passed since work was first begun upon the canal, and yet scarcely a trace of all the magnificent sanitary provision is to be seen. A small provisional hospital of from eighty to a hundred beds is the nucleus around which, presumably, the beautiful system is to be developed. This temporary hospital has a medical staff of seven; and, taking it all in all, cannot be commended for either appointments or service.

Of the inspection divisions and medical districts proposed along the line of the canal, the only visible evidence is a single medical officer, whose duty it is to wander through the unbroken swamps from one excavation to another, gathering the disabled and sending them to the provisional hospital.

Several miles from Panama, on the southeastern side of Mount Ancon, near its base, the permanent hospital of the Canal Company is under construction. *On dit* that Dr. Campayo insisted upon having the building four stories, notwithstanding the latitude and climate, but finally compromised upon three. Little more than the foundation of this hospital has been completed, and no movement has been made toward laying out the grounds, but if the general plan is carried out, the place will certainly be very beautiful and

attractive. One would think that if the pavilion ward is adaptable anywhere, it surely is in the tropics; the director, however, appears to have given it no consideration, and no one on the staff had the temerity to suggest its trial.

This *chef* is a very opinionated and dogmatic man, who thinks that his doxy is orthodox and every one's else doxy heterodox. These personalities are well illustrated by his utter condemnation of quinine as an antiperiodic, and declaration that the clinical thermometer is not only useless, but perniciously misleading in disease.

It was quite impossible to gain access to the records of this service, and truly can I say that never before have I seen a closer corporation. One thing seems pretty evident, however, and that is, that the reports as published so far are garbled and incorrect. It will be remembered that in the report of the president of the American branch of the Canal Company, made several months since, it was announced that a most satisfactory state of health existed among the employees, only twenty-seven deaths having taken place up to that time. I called the attention of the leading physician in Panama to this statement, and he most confidently assured me that it was entirely false, and furthermore, he was in possession of evidence showing clearly that during the eleven months the canal had been under construction, sixty-five officers and eight hundred men had died. I should be loath to reflect in the least upon the verity of this gentleman's assertion, but feel in justice bound to say that it cannot be accepted as conclusive till the statistics are produced. While visiting the foreign cemetery I saw the graves of many of the company's officials, and noticed at the end of a long row an open one covered with canvas. This, the keeper informed me with a grim smile, was for the next dead official, as the company had ordered a grave to be ever in readiness.

From the most authentic sources it is estimated that 10,000 lives were sacrificed in the construction of the Suez Canal, and, *ceteris paribus*, the Panama undertaking should necessitate the expenditure of double that number. So far, foreign and native laborers seem to have suffered alike, though there can be no doubt that the native can stand work in his own swamps better than unacclimated strangers. Next to the Isthmians the Jamaica negroes wear best, and large numbers are being brought over under contract. These two races will build the canal, if M. de Lesseps can raise the money to pay them.

Very truly yours,

ARTHUR C. HEFFENGER.

*Passed Assistant Surgeon U. S. Navy.*

March, 1882.

#### "LOBULAR PLEURO-PNEUMONIA."

MR. EDITOR, — Not having had the pleasure of listening to Dr. Garland's report of his cases of lobular pleuro-pneumonia, and the subsequent discussion, given in the JOURNAL of April 6th, page 319, I should like to call attention to what Trousseau says of what he very justly calls "the crepitant r le of pleurisy," which may be often detected both at the beginning and termination of this disease. He compares an inflammation of the pleura to an erysipelas of the skin, and explains the occurrence of the crepitant r le by the existence of a superficial pulmonary oedema, just as a subcutaneous

oedema accompanies an erysipelas of the surface of the body. The location of the physical signs as described in Dr. Garland's cases is by no means a rare one in cases of pleurisy, and if Trousseau's explanation be correct, an expert in percussion might easily demonstrate the existence of dullness, which would then be due to a superficial pulmonary oedema. I have seen a considerable number of cases both among out-patients at the Massachusetts General Hospital and in private practice, in which a crepitant r le has been present in the location referred to, sometimes on the right side and sometimes on the left. I confess that I have not been able to detect dullness in these cases where the signs have been confined to the region described by Dr. Garland. Perhaps if my tactus were a more erudite one, I might have been able to do so. Later on, however, there has been no difficulty about demonstrating dullness and even flatness both front and back in a certain number of them. In others the crepitant r les (sometimes accompanied by the classical friction sounds) have been present for days or weeks, and have finally disappeared, leaving the patient apparently none the worse. The fact that the r les in some cases extend round to the back need not imply that an effusion will take place. In some of Dr. Garland's cases an effusion occurred, others speedily cleared up, and in still another a bad cough and grave symptoms followed, as is sometimes the case after pleurisy, whether from injury to the lung by pressure, or from an exudation of lymph being followed by an inflammation creeping inwards to the pulmonary tissue — a thing which may occur in adults as well (if not as frequently) as in children.

Yours truly,

F. GORDON MORRILL.

Boston, April 10, 1882.

#### CHIN ON PUBES AFTER VERSION; DECAPITATION; FORCEPS.

MR. EDITOR, — In the Proceedings of the Obstetrical Society of Boston, reported in the JOURNAL, March 2, 1882, Dr. Forster narrates a case of retained head after version, where the chin was resting on the pubes, and where craniotomy was performed to effect delivery.

In a labor case I attended ten years ago, many miles from my home, in Minnesota, a midwife had failed to deliver. I found a woman in her eighth labor at term, with the largest vagina I have ever seen, — abnormally large — possibly already much distended by the midwife's hand; a dead child lying in a heap in the uterus, approximating a vertex presentation; the placenta blanched and loose in the womb; and no hemorrhage. Having anesthetized the woman I attempted in vain to deliver by forceps, though probably, in spite of all difficulties, my inexperience or unskillfulness was chiefly to blame. I cannot remember at this remote date the dimensions of the superior strait (and my notes of the case are stored in a distant State), though it was certainly not greatly contracted, nor yet roomy in keeping with the vagina. A house full of children vouched fairly for successful deliveries in the past.

I then turned the child by the regular rules, and nothing was easier with such a voluminous passage, but the occiput and chin rode on the pelvic margin. I again tried forceps without success, for now the head could not be flexed. Instruments for craniotomy were not

available. The shoulders were outside, and the base of the neck just accessible at the vulva.

With a bistoury I cut through the soft tissues of the neck, carefully guarding the vulva, and with a stout pocket-knife severed the spinal column. Then it was easy to push up and tilt the head until the occiput presented, when I applied the forceps, and placing one finger on the ragged vertebra to protect the vaginal wall, I readily withdrew the child. At the midwife's request I stitched the head to the trunk before leaving.

The woman made a good recovery. During the operation my only assistant, besides the midwife, was an amiable railroad contractor whose grading passed through this patient's farm.

FRANCIS H. ATKINS, S. B., M. D.

A. A. Surgeon, U. S. Army.

FORT STANTON, NEW MEXICO.

### THE McLEAN ASYLUM.

We are glad to quote from the last report of Dr. Cowles the following account of the improvements going on at the McLean Asylum for the Insane at Somerville:—

The work of renovation and repairs, for the purpose of putting all parts of the Asylum in a thoroughly comfortable condition, has been diligently carried on during the past year, notwithstanding the purpose of building a new asylum elsewhere in the near future. Not only this, but, as the work proceeds, all practicable alterations of construction, with the introduction of modern improvements for increasing the comfort and attractiveness of the wards, are being made. For example, one of the oldest of the women's wards in the Asylum, being a long and rather dark hall, with a window at one end and rooms on either side, has been changed in its whole aspect, and made cheerful and pleasant by the use of bright colors in its decoration, by plants and birds, and by an alcove in place of one of the rooms on the sunny side of the house. A window as wide as the alcove, and extending from floor to ceiling, has panes of ordinary glass 17x29 inches in dimensions, and is so arranged as to be opened both at top and bottom twenty-nine inches. These open spaces are covered by outside screens of fine wire gauze, such as is customarily used in the windows of private houses in the summer season. Some windows in other wards and rooms have, during the past two years, been protected in the same way, in place of the iron guards, which have been removed. The objection to the common plan in foreign asylums, of limiting the opening of windows to five or six inches, which is inadmissible during the hot summer months in this climate, is thus overcome.

The dining-room of the reconstructed ward above described has been decorated in bright colors, and the iron guards removed from the windows, which have been fitted with large panes of glass, together with some small colored ones, giving a pleasing effect. A similar change is being made in the chambers of the ward as to the removal of guards and use of large glass in the windows, which are here provided with concealed shutters, for use in cases requiring them, but so constructed that the windows may be left fully open, and the fresh air may freely enter the rooms during the night in hot weather.

Similar alterations, introducing alcoves, changing

windows, etc., are in progress in other wards, to the effect of letting in more sunlight and fresh air, and greatly increasing the cheerfulness and comfort of the house.

Some progress has been made in the direction of enlarging the freedom of patients. A door leading from the five principal wards for men has been fitted with an ordinary handle, and remains unlocked nearly all day, permitting free egress of the occupants of those wards to the large garden, which is not a secure inclosure. Two persons only have taken advantage of this opportunity to escape, and one of these returned voluntarily in a few days.

Since early in the year, the door of the Appleton ward for gentlemen has been left unlocked during the day. This building stands upon the open grounds of the Asylum; and, though its door is unlocked and some of its windows are without guards, no trouble has arisen in consequence.

Wardmaids are now employed, after the manner of the training schools for nurses in general hospitals, in all the female wards of the house. As a consequence, the attendants, being relieved of a good deal of their former work, have more time to devote to the patients, and are made more strictly nurses and companions of the sick.

In the male wards also, some important results have been gained. On a few occasions heretofore, the wife of a supervisor has been allowed to reside here, and has had some special duty given her. A few years ago a nurse was placed in one of the wards, where she had the care of the dining-room and some association with the patients, and the results gave some favorable indications. During the past year, the plan of employing female nurses in the men's wards has been successfully developed and its possibilities established. There are now four women employed in the male wards whose duties require their presence there at all times of the day and evening. From the experience gained here in associating nurses with insane men, I am able to say that there is no reason why this cannot be done with great benefit in all our wards, excepting one for some special cases.

The introduction of medical internes, a year and a half ago, has proved a very satisfactory and valuable addition to the medical staff. Two such officers act as clinical clerks, make daily visits to the wards, and do other clinical work, such as is required in general hospitals.

### TRAINING VERSUS "EDUCATION."

It is hopeless to expect, remarks the *Lancet*, February 25th, that the mental and physical disadvantages accruing to our modern system of "education" will be sensibly reduced until it begins to be recognized that education should consist in the development of the faculties rather than the mere acquisition of knowledge. It may appear a paradox, but it is a simple and plain statement of fact, that a man may be well educated, and yet know little or nothing. The best intellectual organism is not that which has been most heavily charged with information, but that which possesses in the highest degree the faculty or power of finding facts at pleasure, and using them logically and with prompt ability. A ready wit, in the true sense of the term, is incomparably better than a loaded brain. Attention is frequently drawn to this matter in our columns, and

the lay press does us the honor to quote and amplify our remarks on the subject, but little, if anything, is gained by the ventilation of the idea, because it is opposed to the spirit and feeling of the day. So much the worse for the prevailing sentiment on the subject. Our appeal must now lie to parents and teachers. Miserable cases of mental collapse are constantly falling under notice in which the process of cramming has produced a blighting effect on the brains of the young.

Their physical health has been sacrificed in the attempt to make them prodigies of learning. It would be more reasonable to remember that the brain is not only as much part of the body as is the muscular system, but the organ of the mind is so intimately connected with the centres of vitality, that unless the whole body be fully nourished the brain must quickly lose its strength, and the mind power itself be exhausted in the loss of general health.

## REPORTED MORTALITY FOR THE WEEK ENDING APRIL 8, 1882.

| Cities.                          | Population by Census of 1880. | Reported Deaths in each. | Deaths under Five Years. | Percentage of Deaths from         |                |                       |                |            |

Deaths reported 2995 (no report from New Orleans): 1145 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 707, consumption 417, lung diseases 436, diphtheria and croup 185, scarlet fever 147, small-pox 95, measles 62, typhoid fever 55, diarrheal diseases 38, whooping-cough 35, cerebro-spinal meningitis 27, malarial fevers 27, puerperal fever 15, erysipelas 14, typhus fever seven. From *measles*, New York 29, Chicago 11, Philadelphia eight, Brooklyn seven, Cincinnati and Pittsburgh two each, St. Louis, Baltimore, and Milwaukee one each. From *typhoid fever*, Philadelphia 16, Cincinnati six, Chicago and St. Louis five each, Baltimore, Pittsburgh, and Buffalo three each, New York, Brooklyn, Boston, Milwaukee, Providence, New Haven, Charleston, Nashville, Lowell, Worcester, Lawrence, Springfield, Somerville, and Milford one each. From *diarrheal diseases*, New York 10, St. Louis nine, Chicago five, Baltimore four, Brooklyn, Boston, Cincinnati, and Holyoke two each, Buffalo, and Charleston one each. From *whooping-cough*, New York 13, Brooklyn four, Chicago three, Philadelphia, Boston, St. Louis, Pittsburgh, and Haverhill two each, Buffalo, Providence, Lowell, Cambridge, and

Lawrence one each. From *cerebro-spinal meningitis*, Buffalo eight, New York five, Chicago three, Philadelphia, Boston, Cincinnati, Pittsburgh, Providence, New Haven, Nashville, Fall River, Salem, Gloucester, and Waltham one each. From *malarial fevers*, New York 12, Brooklyn eight, St. Louis four, Chicago two, and Buffalo one. From *puerperal fever*, Brooklyn three, New York, Boston, St. Louis, and Buffalo two each, Chicago, Baltimore, Milwaukee, and Newton one each. From *erysipelas*, New York five, Philadelphia three, Boston two, Brooklyn, Chicago, Cincinnati, and Providence one each. From *typhus fever*, New York six, Baltimore one.

One hundred and thirty-five cases of small-pox were reported in Cincinnati, Pittsburgh 17, Baltimore 14, St. Louis 13, Brooklyn, Boston, and Buffalo each two, Milwaukee one; diphtheria 32 cases, typhoid fever seven, scarlet fever six, in Boston; scarlet fever 12, and diphtheria four, in Milwaukee.

In 35 cities and towns of Massachusetts, with a population of 1,040,848 (population of the State 1,783,086), the total death-rate for the week was 22.83 against 21.80 and 21.50 for the previous two weeks.

For the week ending March 18th, in 173 German cities and

towns, with an estimated population of 8,344,329, the death-rate was 27.4. Deaths reported 4393: under five 2146; pulmonary consumption 656, acute diseases of the respiratory organs 511, diphtheria and croup 241, scarlet fever 101, whooping-cough 61, typhoid fever 49, measles and r  theln 38, puerperal fever 23, small-pox (Dortmund, Essen eight) nine, typhus fever (Danzig, Posen) two. The death-rates ranged from 14.6 in Stettin to 42.9 in Angsburg; K  nigsberg 29.1; Breslau 37.8; Munich 41.9; Dresden 25.9; Berlin 26.2; Leipzig 27.3; Hamburg 27.2; Hanover 20; Bremen 19; Cologne 26.2; Frankfurt 28.5; Strasburg 30.7.

In the 28 English towns, with an estimated population of 8,457,514, for the week ending March 25th, the death-rate was 23.7. Deaths reported 3842: acute diseases of the respiratory

organs (London) 427, whooping-cough 251, measles 162, fever 65, scarlet fever 64, diarrh  a 52, diphtheria, 24, small-pox (London 13) 14. The death-rates ranged from 16.2 in Cardiff to 30.2 in Manchester; Leeds 19.3; Bristol 19.6; Liverpool 22.4; London 24.5; Sheffield 25.3.

For the week ending March 25th in the Swiss towns, population 479,934, there were 49 deaths from acute diseases of the respiratory organs, pulmonary consumption 47, diarrh  al diseases 18, diphtheria and croup 15, scarlet fever six, whooping-cough five, typhoid fever three, puerperal fever two. The death-rates were, Geneva 29.3; Zurich 34.3; Basle 27.7; Berne 32.2.

The meteorological record for the week ending April 8th, in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the U. S. Signal Corps:—

| Date.            | Barom-eter. | Thermom-eter. |       |          |          | Relative Humidity. |            |             |       | Direction of Wind. |            |             | Velocity of Wind. |            |             | State of Weather. <sup>1</sup> |            |             | Rainfall.             |                   |

## UNUSUAL RESULTS OF VACCINATION.

PH  NIX, MICH., April 5, 1882.

MR. EDITOR.—In your issue of March 23, 1882, there are detailed several cases of unusual results of vaccination. I here-with give you a much larger number of similar cases. Since January 1st I have performed over 800 successful cases of primary vaccination, using nothing but bovine virus; among that number there have been 68 cases with an eruption of dusky red color, covering nearly the whole surface of the body. The eruption was slightly raised, somewhat resembling measles; in fact, my attention was called to it by the parents thinking that the children had the measles. A few small vesicles scattered among the patches of eruption only could be seen. The patients all complained of an intense itching. I also performed 13 successful primary vaccinations with humanized virus one remove from the heifer, and among that number three had the above eruption. Among over 200 successful revaccinations I have not seen any eruption.

The eruption in the above cases passed away in a few days, leaving a brownish tinge of the skin where it had been, which also disappeared in a few days more. My brother practitioners in this neighborhood have had similar experiences this winter.

Yours truly, A. I. LAWRENCE, M. D.

## OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM APRIL 8, 1882, TO APRIL 14, 1882.

GREENLEAF, CHARLES R., major and surgeon. Relieved from duty in Department of Dakota, to proceed to New York city, and on arrival report by letter to the Surgeon-General. S. O. 78, A. G. O., April 5, 1882.

WOODHULL, A. A., major and surgeon. Now awaiting orders; to report in person to the commanding officer of the recruiting depot, David's Island, N. Y. H., for duty at that post. S. O. 78, C. S., A. G. O.

WILLIAMS, JOHN W., major and surgeon. Relieved from duty in Department of the Missouri, to proceed to Washington, D. C., and report to the Surgeon-General. S. O. 78, C. S., A. G. O.

WATLES, W. E., major and surgeon. Relieved from duty in Department of Texas, to proceed to Washington, D. C., and report to the Surgeon-General. S. O. 78, C. S., A. G. O.

JAQUETT, G. P., major and surgeon. Relieved from duty at David's Island, N. Y. H., to proceed to his home and report by letter to the Surgeon-General. S. O. 78, C. S., A. G. O.

BROWN, J. M., major and surgeon. Relieved from duty in Department of the Missouri, to proceed to Cincinnati, Ohio, and on arrival report by letter to the Surgeon-General. S. O. 78, C. S., A. G. O.

CLEARY, P. J. A., captain and assistant surgeon. Relieved from duty in Department of the East, and, on expiration of his present sick leave of absence, to report by letter to the Surgeon-General. S. O. 78, C. S., A. G. O.

CROSKILITE, H. M., captain and assistant surgeon. Granted leave of absence for four months from June 1, 1882. S. O. 80, C. S., A. G. O.

CARVALLO, CARLOS, captain and assistant surgeon. The extension of his leave of absence on surgeon's certificate of disability granted him in S. O. 256, November 12, 1881, from A. G. O., is still further extended six months on account of sickness. S. O. 80, A. G. O., April 7, 1882.

BYRNE, CHARLES B., captain and assistant surgeon (Fort Barrancas, Fla.). Assigned to temporary duty at Mt. Vernon Barracks, Ala., during absence of Assistant Surgeon Cunningham. S. O. 41, Department of the South, April 12, 1882.

FINLEY, captain and assistant surgeon. Having reported at these headquarters, is assigned to duty at Fort Concho, Texas. S. O. 35, Department of Texas, April 8, 1882.

MOSLEY, E. B., captain and assistant surgeon. Relieved from duty in Department of the Platte, to proceed to New York city, and, on arrival, report by letter to the Surgeon-General. S. O. 78, C. S., A. G. O.

MAUS, L. M., captain and assistant surgeon. Relieved from duty at David's Island, N. Y. H., and to report in person to the commanding general, Department of the Missouri, for assignment to duty. S. O. 78, C. S., A. G. O.

KILBOURNE, H. S., captain and assistant surgeon. Relieved from duty in Department of the East, and to report in person to the commanding general, Department of Dakota, for assignment to duty. S. O. 78, C. S., A. G. O.

TAYLOR, M. E., captain and assistant surgeon. Relieved from duty in Department of the Missouri, to proceed to St. Louis, Mo., and, on arrival, report by letter to the Surgeon-General. S. O. 78, C. S., A. G. O.

SPENCER, WM. G., captain and assistant surgeon. Granted leave of absence for four months, with permission to apply for an extension of two months. S. O. 80, C. S., A. G. O.

## Original Articles.

## A CLINICAL CONTRIBUTION TO THE DIAGNOSIS OF POTTS' DISEASE OF THE SPINE BEFORE THE STAGE OF DEFORMITY.

BY V. P. GIBNEY, M. D.,

*Of the Hospital for the Ruptured and Crippled, New York.*

THIS paper is a supplement to one published in the *JOURNAL* March 9, 1882, and is intended to illustrate many of the points upon which I dwell in that communication. The illustrations will of course be clinical, and I have had considerable difficulty in selecting from the rich storehouse of recorded material our hospital affords such cases as will meet the requirements of a practical article.

In recording errors of my own making, as well as those my confrères have made, I but emphasize the value of diagnosis much more forcibly than if I recorded case after case wherein our skill had enabled us in every instance to arrive at a correct diagnosis. In medicine, as in the sporting field, there are very few men who can hit the mark every time. Long and constant practice does not make perfect, in the true sense of the term, but simply approximates perfection. I do not believe that there is any man, be his speciality what it may, who does not meet with cases and examine them over and over again, only to confess his ignorance as to the lesion. Such cases make the science of medicine attractive. They stimulate study. The two following have been to me extremely interesting, and because a solution has not been reached in my own mind I hesitated to publish them, yet they so well illustrate the remarks I have just made, that I decide to submit them as "a study."

CASE I. FIRST DIAGNOSIS, A STRAIN; FIVE MONTHS LATER, A SUBACUTE DORSO-LUMBAR MENINGITIS, OR NEUROSIS OF THE HIP; TWO YEARS LATER, IDIOPATHIC ILIAC ABSCESS; A MONTH LATER, LUMBAR CARIES WITH PSOAS ABSCESS; AT PRESENT WRITING "(?)"

Grace H., aged eight, came under observation in the out-door department of the hospital October 7, 1879. She was disinclined to bend the dorso-lumbar spine either in stooping or walking, and referred what pain she had to this region. There was no angular deformity of the spinal column, and, indeed, no exaggeration in any of the normal curves. She had no abdominal pain, and none in the distribution of the lumbosacral nerves. Her rest at night was broken by the pains above mentioned. Three weeks ago, while sound in health and limb, she fell backward from a chair, and the mother could not find any bruise. Pain was felt in the spine, yet she continued at school for a week. It was considered a mere spinal strain, but as a precaution we applied a brace.

October 27th. Is doing well; there is no deformity; she walks naturally, yet does not want to leave off the apparatus.

January 10, 1880. No sign or symptom of disease, and the brace is removed tentatively for two weeks.

January 24th. Since last visit the pain and stiffness have returned, and yesterday she lay down all day. There is no kyphosis and no tenderness, but the brace is reapplied.

February 2d. Comes this morning with slight limp, left side, and refers pain to her hip while she has no

pain at the knee. Blister ordered to dorso-lumbar spine.

February 21st. Entirely relieved; no pain, no lameness, no spinal stiffness.

May 2d. Nothing whatever save an occasional lumbar pain and a scalding sensation on micturition. An alkaline diuretic ordered.

February 4, 1882. First visit since April 11, 1881, at which time she was considered cured. Comes now because she favors the left thigh in walking, and on examination there is found marked tumefaction in left iliac fossa, but no other evidence of spinal caries. A liniment and roller ordered.

February 25th. Walks with heel squarely on the floor and she is relieved.

March 18th. There seems to be an unmistakable caries of last dorsal and first lumbar vertebrae, as concussion gives pain, and the tumor in iliac fossa is increasing. Yet there is no deformity of spine; a brace is ordered, and on the 25th is applied. Within a few days the signs have disappeared—all save the tumor—and this is smaller. What is the lesion?

CASE II. DIAGNOSIS FIRST VISIT, HIP-DISEASE (?); AT FIFTH VISIT, A MONTH AFTERWARDS, CARIES OF THE LUMBAR WITH PSOAS ABSCESS; NO SIGNS OF ANY DISEASE AT THE END OF A YEAR.

Cornelius K., aged three, was examined rather hastily in the out-door department, February 11, 1881. The hour was late, and all we learned was that the boy had been walking lame for three weeks, and had complained during that time of pain in his limb. The movements at the left hip could not be made with ease, and the diagnosis was recorded "left hip-disease (?)," and the mother was instructed to bring him again on the 14th, which she did, and it was further learned that he was stiff in the morning, but had had no pain night or day since her visit on the 11th. The hip movements were limited only in extension, and there seemed to be a little atrophy of the limb. A spica bandage was applied, and the patient was ordered to be brought on the 17th. Nothing further was elicited on that date, although he was submitted to a very careful examination. On the 23d nothing conclusive could be found, and on the 28th I felt pretty sure that I found a little deep-seated induration in the iliac fossa, but its existence could not be demonstrated, so exceedingly cross was the child. March 12th he walked like one with spinal disease, favoring too the left side; he stooped, however, quite naturally, and sitting, standing, or lying, no prominence or other deformity of the spine could be detected, except an almost inappreciable lordosis. There was no tenderness on concussion, and the lateral movements were good. The iliac tumor was now easily mapped out and was the size of a hen's egg. On the 26th there was no change, and the diagnosis was given as vertebral disease with psoas abscess, a spinal brace being applied. The patient was examined a week or two later with but confirmatory results, and then we lost sight of him until April 1, 1882, when the mother brought him to the office by request. The spinal brace had been removed six months ago, as she saw no further necessity for its use. There is now no sign of spinal caries, and no tumefaction of any kind can be found in the iliac fossa. He walks without any lameness, and the functions of the joint seem perfect. He is fat and hearty. The only thing which suggests itself now as the lesion from which he

suffered a year ago is idiopathic psoriasis terminating in resolution.

That one may see how insidiously a spinal caries may go through all its stages even, and be recognized only after a spontaneous cure has taken place, the following is presented.

CASE III. OLD DORSO-LUMBAR CARIES WITH PROJECTION OF ONE AND A QUARTER INCHES FROM THE VERTICAL AXIS; CICATRIX OF ABSCESS; COMES ON ACCOUNT OF A LATERAL CURVATURE WHICH IS COMPENSATORY; NEVER ANY TREATMENT, AND NEVER ANY DIAGNOSIS (?).

Katie O'C., aged seventeen, applied at the hospital August 23, 1879, for the relief of a lateral curvature of the spine which was most marked in the dorso-lumbar region and to the left, there being very little rotation of the bodies present. There is found an angular deformity in this region, the projection backwards being one and a quarter inches, and ankylosis seems to be well established. The remaining portion of the column is normal in function, she can stoop with ease, is in excellent health, and never has any pain. There is the cicatrix of an abscess in right loin. No one looking at her as she is dressed would ever suspect that there was any deformity. The history as given by the mother is, that two years ago or more there was observed a certain degree of stiffness as the girl would attempt to stoop, in fact she stooped without bending the back at all. There was very little pain, and the parents, regarding this as a "foolish habit" into which the daughter was falling, made her "bend the spine like anybody else." After a while an abscess appeared under the floating ribs on the right side, pursued the usual course, and finally healed. It is reported that the discharge of matter was very profuse, and that the patient had a little fever. The disease went as it came. We kept her under observation for awhile to satisfy ourselves that a cure had really taken place, and she then ceased reporting.

#### I. THE CERVICAL AND CERVICO-DORSAL VERTEBRÆ.

CASE IV. DIAGNOSIS OF CERVICAL POTTS' WITH AN "(?)" ; CURE IN SIXTEEN DAYS; DEVELOPMENT OF FURUNCULI AND CASE BECOMES CLEAR.

On the 4th of August, 1881, my friend, Dr. Holt, referred to me Martin F., aged four, from the children's department of the Bellevue Dispensary. The doctor, like myself, thought the boy should have the benefit of any doubts that might exist concerning vertebral disease, because he had had scarlatina about two months previously, and during convalescence began to complain of pain in the neck, and to carry the head in torticollis, which deformity had been increasing; because, furthermore, he had not rested well nights, and had complained of cervical and post-occipital pain if the head were moved. On my day record I noted, caries of the cervical vertebrae (?), although I could not detect any deformity in spinous processes or lateral masses unless I flexed the head forward toward sternum. I was further induced to believe in a probable caries because I knew that the exanthemata very often induce a cachexia which is peculiarly fertile for the development of bone diseases. A spinal brace with head-spring was ordered for the 16th, on which date the apparatus was applied, the boy having been kept at rest in the mean while. By the 20th his deformity had

disappeared, the functions of the head were normal, and there was a crop of furunculi in the post-cervical region. Fears were abandoned, the brace was removed, and the syrup of the iodide of iron, in ten-drop doses three times a day, ordered. The patient was seen on the 27th and on September 5th, the notes on which dates are unnecessary as the boy was doing well.

October 5th. Since the date of last note a large furuncle has formed and opened over the spinous processes, and the cicatrix remains. Discharged cured.

CASE V. CERVICAL CARIES NOT DISCOVERED UNTIL A POST-PHARYNGEAL ABSCESS GAVE ALARMING SYMPTOMS; DIPHTHERIA SUSPECTED AND TRACHEOTOMY SUGGESTED.

Joseph O'C., aged four years, was brought to the hospital March 30, 1878, by the mother, in great alarm. She brought also a letter from a medical friend of mine asking an opinion. When he had been first called to the child the distress was so great that he fancied he had a case of diphtheritic croup, and began to prepare for tracheotomy, but on closer examination the case appeared more like one of post-pharyngeal abscess, and he sent it forthwith to me for consultation. The little patient was breathing stertorously, had a high temperature, and had been in much distress for twenty-four hours. The head was held in slight rotary torticollis, and the mother told me that this deformity had existed for "some time." I had great difficulty in getting an examination of the pharynx. The left tonsil was much enlarged, and was covered with a whitish, glairy mucus, not unlike a diphtheritic membrane, but back of the tonsil I could see the outlines of a tumor. The spine was held stiffly, and there was a shade of fullness in the spinous processes. I sent the patient direct to the doctor's office with advice to incise the abscess, which he did that very morning, getting a large quantity of pus. The relief, he wrote me, was immediate, and on the 10th of April I applied a head-spring. The vertebral caries was soon fully established, and on October 19th I detected an abscess in the right cervical triangle, and opened it on December 30th. The further history is interesting but not pertinent. March 7, 1881, the case was discharged cured.

CASE VI. A CERVICAL NEUROSIS, PROBABLY MENINGEAL, FIRST DIAGNOSTICATED AS VERTEBRAL CARIES; PROMPT RELIEF, AND RETURN OF SYMPTOMS FIVE YEARS LATER; RELIEF AGAIN.

Joseph C., aged twelve, was brought to the out-door department August 21, 1881, and the following notes were made in the daily record: Torticollis quite marked; rotation of head to the left, the mental process of the inferior maxilla being three inches from the acromion process of the scapula. Passive movements are resisted, and are very painful; there is decided tenderness on pressure over the spinous processes of the cervical vertebra, but there is no deformity in this region. The family history is reported as good on both sides; there are eight children living, and all are in good health; two died in early infancy. The mother reports that he was under treatment at this institution four years ago, and on referring to the records we find that he was examined for the identical set of symptoms on the 25th of August, 1876, that a diagnosis of

cervical caries was made, that a brace and head-spring were applied on the 29th, that he reported on September 12th and October 3d of same year, and was not seen again. She states now that the apparatus was removed on the last date, and that the case was discharged cured. He continued without an untoward symptom until four days ago, August 20th, when he became drowsy, and next day came in with his head distorted, and complaining of pains in his neck and back. He also had headache and cramps in hands and legs, attended with marked numbness. He has been gradually growing worse. Caries is excluded on the present occasion, and the lesion is thought to be a meningeal hyperæmia. A fly-blister is ordered, and on the 31st it is recorded that he has obtained very little relief. The blister, however, was not applied where ordered, and another is to be applied. Admission to the hospital is also advised. September 10th is admitted, but an examination is not made until the evening of the 12th, when we have difficulty in recognizing any deformity. He executes all the movements of the head easily, and there is no spinal tenderness or deformity. In fact the patient is cured! He was retained in hospital until the 23d, during which interval not a sign of relapse could be seen. The diagnosis recorded on the 12th was: torticollis due to perispondylitis cervicalis rheumatica.

On reflection it seems now that his symptoms may be explained in one of two ways. There may have been a meningeal hyperæmia due to rheumatic influences or to malarial poisoning (the boy has always lived on Staten Island, where malaria is said to prevail in protean types); again, it may have been a lesion affecting the ligamentous structures about the foramina of exit for the cervical nerves, and the nature of the lesion may have been either rheumatic or malarial.

## II. THE DORSAL VERTEBRE.

### CASE VII. A NEUROSIS DIAGNOSTICATED AT FIRST; PROVED TO BE DORSAL CARIES A MONTH LATER; SPINAL TENDERNESS AND MALARIAL HISTORY.

Flora D., aged six, an anæmic child, came under observation in the out-door department February 14, 1881. She complained much of pain in the back, was at times stiff in her gait, and there was on this date very marked spinal tenderness in dorso-lumbar region and over sacrum. The joint movements were all free and painless, and there was no tenderness on concussion. A full history was not obtained, as the patient came in late. A diagnosis of spinal neurosis was made, and a blister ordered.

February 23d. No tenderness now on direct pressure, but if pressure be made on the head in the long axis of the body the girl complains of pain in the lumbar region. A tonic ordered, and patient to report in a week for further observation.

March 14th. Dr. Knight sees the case to-day, and diagnosticates incipient caries of the spine; a brace is accordingly ordered, and applied a few days later.

September 27th. There is an angular deformity at junction of mid and lower dorsal region, the height of which is three eighths of an inch. She complains of pain in the back, and the brace is out of repair, so a new one is ordered.

December 29th. There is a clear history of malarial poisoning; periodical headaches; chilly sensations,

etc., etc. (Patient lives in Greenpoint, Long Island.) Quinine, gr. vi. *per diem*, and to be increased.

February 23, 1882. The mother reports that the child was promptly relieved, and the medicine was shortly afterward discontinued.

March 13th. Periodic headaches again; quinine ordered, and relief soon afforded. The spinal deformity has not increased at present writing, and the disease seems arrested.

### CASE VIII. INTERCOSTAL NEURALGIA (?) WHICH PROVED TO BE SYMPTOMATIC OF AN UNRECOGNIZED VERTEBRAL CARIES.

Fred. C., aged thirty-two, applied June 22, 1881, near the end of the morning clinic, for relief of distressing pains, which he referred to the thoracic walls and hypogastrium. I made a hurried examination, finding a very tender dorsal spine, and tenderness over intercostal nerves. Fowler's solution and counter-irritation were ordered, and he was given explicit instructions to call in a few days for a more thorough examination. His first visit after the above date was on December 24, 1881, when he came walking into the office stooped over like an old man, and bearing the following note from my friend, Dr. Ripley: "Dear Doctor, You saw this man four months ago, *he says*. I should like your more mature opinion. Truly yours, J. H. R." It didn't require any mature opinion now for a diagnosis; the kyphosis spoke for itself. I learned from the man, though, that when he went home on the morning of June 24th his wife took charge of the case, and said he shouldn't take any "poison," and shouldn't have his back blistered, so he never came back for the examination I had requested; but when he began to suffer more, and to grow stooped, he went to his family physician, who sent him back to the hospital. His spinal tenderness on the first visit misled me, and this fact, taken in connection with the lack of time, prevented me from making an examination which would, without doubt, have led to a correct diagnosis. It is a noteworthy fact, however, that his pains have been in exacerbations, and that they usually follow exposure to wet and cold. He works in an engine room-house, and is much exposed to great changes of heat and cold, frequently getting his feet wet. I do not mean to intimate that the pains in joint disease do not, as a rule, come in exacerbations, but the above facts may help to account for tender points not only over the spine but along the dorsal nerves.

### CASE IX. SIMPLE ANTERO-POSTERIOR CURVATURE OF RACHITIC ORIGIN.

Jane H., aged twenty-two months, is but one of a large number of children brought to the hospital for spinal caries. This child is presented February 12, 1879. There is a marked exaggeration of the dorsal curve, and the child is unable, by reason of this malposition, to stand alone. The epiphyses of the long bones are enlarged, and the history is so clearly rachitic that we have no difficulty in making a diagnosis of rachitic kyphosis; besides, the curvature can be overcome by traction. A light steel brace is applied to overcome the deformity, and further treatment is constitutional. The progress was comparatively slow, and it was not until January 29, 1880, that all deformity had disappeared, and the child was walking freely. The apparatus was removed, and a careful examination failed to discover any signs of bone disease.

**CASE X. FIRST DIAGNOSIS, LATERAL CURVATURE FROM RACHITIS; ELEVEN MONTHS LATER SPINAL CARIES DETECTED.**

Jas. C., aged four, was admitted to hospital July 24, 1874. He had a bad family history, and his personal history was wretched. The child had a chronic blepharo-adenitis with pannus, and it was not long since he had had the measles, with slow convalescence. During this convalescence he began to walk unsteadily. He stands with body shifted, as it were, over to the side of the pelvis, his abdomen is tympanitic, and there is no angular prominence or exaggeration of normal curves. An apparatus was applied, and constitutional treatment was faithfully carried out. The blepharo-adenitis gave much annoyance, and his improvement was often interrupted, so that by June 27, 1875, we had nothing specially encouraging to report. His lateral curvature had been overcome, but now he was observed to stoop very stiffly and with great effort; there was marked lordosis and slight tenderness on concussion, the pain being referred to the dorso-lumbar region.

A diagnosis of vertebral caries was readily made, and a better-fitting brace applied. A mere "knuckle" finally appeared, and the correctness of the diagnosis was established beyond doubt.

### III. LUMBAR VERTEBRÆ.

**CASE XI. LUMBAR CARIES DIAGNOSTICATED AS HIP DISEASE.**

William W., aged five, seen in out-door department January 24, 1881, and examined by Dr. Geo. W. Ryan, of the house-staff. The doctor found a pre-natural immobility of the spinal column, and a slight fullness rather than lordosis in lumbar region. He did not find any tenderness on pressure or concussion, but made a diagnosis of lumbar caries, and ordered a brace.

February 18th. Within a few days the little patient has walked lame, favoring the right limb. An elastic tumor, nearly as large as a hen's egg, is discovered deep in the right iliac fossa, and the lameness easily explained.

March 4th. Was taken to Bellevue Hospital about ten days ago, and one of the senior members of the house-staff examined him with much care. The father reports that the doctor said the boy had no spinal disease, but had hip disease, and advised admission to hospital. Another member of the staff, who was present on that occasion, gave me the same report. On examination to-day we find the hip movements smooth, and resistance only in extension. The father will not keep the apparatus applied as directed.

The spinal prominence on January 5, 1882, was one-half inch, and the psoas abscess was quite conspicuous.

CASE XII. is very like the one just reported. I had made a diagnosis of caries and had applied a brace, — had also recognized a deep induration in iliac fossa. The boy walked lame, and the family physician, a man of much local prominence in a neighboring town, wrote me requesting that I examine closely for hip disease.

I did so at the doctor's request. The further development of the case abundantly sustained me in the diagnosis I had made.

**CASE XIII. THE EFFECTS OF TRAUMATISM; SYMPTOMS RELIEVED BY COUNTER-IRRITATION; EXAMINED THREE YEARS AFTER CURE AND NO RELAPSE HAD OCCURRED.**

Warren B., aged seven, came under observation January 4, 1877. He had fallen in September, 1876, striking his back against the edge of a stone and complained immediately of severe pain. After a few days the pain passed off, and he had no further trouble of any kind until the 9th ult., when, after a long walk, he experienced a marked weariness in his back, and this was followed by pain. On examination we found decided tenderness on pressure over the spinous processes, but none on concussion of the spine or on passive motion. His mother reports that when he was two years of age he had hip disease, and was cured by the weight and pulley in three months. No evidence about the hip can be discovered now of any such disease ever having existed. The diagnosis of the spinal lesion is caries of spine (?) incipient, and "probably not" was added. A fly blister was ordered, and at next visit a brace was applied by way of precaution. — March 14th. Not an untoward symptom since the first visit. — April 8th. Discharged cured.

April 24, 1880. Examined and found sound in body and limb. Has never had any signs of relapse.

### CASE XIV. PERINEPHRITIS.

Jno. Jos. C., aged four and a half, was admitted to hospital July 15, 1880. The maternal family history was phthisical. Five weeks ago the boy began to complain of his back, and to manifest a little stiffness on stooping. Two weeks ago he began to walk lame, and for the past five or six days the parents have observed a slight swelling in the right loin. He has been losing flesh. The spine is held rigidly as he walks, and he leans over toward the right side. There is no mobility in the spine as he attempts to stoop. Filling the right ilio-costal space and extending over the brim of the pelvis is an irregularly circumscribed swelling which gives deep fluctuation at one point, and is very tender to pressure. The thigh can be extended to nearly 180° without pain or resistance. It can be completely flexed, ab- and adducted, and rotated with very little effort. There is no induration in the iliac fossa, and the thighs are equal in size. A diagnosis of perinephritis is made, and August 5th the abscess is opened by incision. A tent was then inserted, and the boy was up next day. — August 16th. Sac pretty well collapsed, and the opening of the sinus has a pointing appearance so characteristic of bone disease. There was scarcely a trace of constitutional disturbance at any time, and on November 9th it is recorded that the sinus has closed. — November 19th. Functions of hip and spine normal, and the case is discharged cured.

In the former paper I had occasion to speak of an osteitis affecting the epiphyses of the long bones which often obscured Pott's disease in its incipency. In looking over our records for the past ten years, I find Pott's disease of the spine associated with disease of the joints more frequently than one would suppose; in fact, there are thirty-five cases distributed as follows: —

|   |    |
|---|----|
| Vertebral caries associated with hip disease            | 11 |
| Vertebral caries associated with knee disease           | 10 |
| Vertebral caries associated with ankle disease          | 10 |
| Vertebral caries associated with ankle and hip disease  | 1  |
| Vertebral caries associated with shoulder disease       | 1  |
| Vertebral caries associated with knee and ankle disease | 2  |

A single case of multiple arthritis will serve to illustrate the obstacles in the way of making a diagnosis.

CASE XV. CARIES OF THE ANKLE; SYMPTOMS OF SPINAL CARIES TWELVE MONTHS AFTER INVASION OF ANKLE DISEASE; MALARIAL COMPLICATIONS MASKING THE SYMPTOMS OF BONE DISEASE; SYNOVITIS OF BOTH KNEES NINE MONTHS LATER.

Harold S., aged three, came under treatment as an out-patient, December 3, 1879, with a history of lameness dating from the preceding April. The only one of the exanthemata he had had was pertussis, and this was in June, 1878. He is the third of five children, the eldest being a mute, and all are delicate. The father is reported to be rheumatic, and the grand-mother to have died of apoplexy. The maternal grand-mother and an aunt died of consumption. The mother herself is aught but healthy. The patient lives in Jersey City. The infiltration about the ankle was well marked, and the joint movements were limited to very small arcs. He was put on the iodine treatment internally and externally, and a moderate amount of rest was enjoined. February 18, 1880, for symptoms of malarial poisoning, quinine was ordered, and he was soon relieved. He attended very irregularly during the next six months, in fact he was examined April 6th, and not again until August 10th, when there were some signs of spinal caries; that is, he had pain at the epigastrium and a stiffness of the spinal column, but there was marked spinal tenderness. He had also a ravenous appetite. A blister was ordered to the spine, and on the 17th the only symptom that had disappeared was the spinal tenderness. His mother brought a specimen of his urine on the 30th. It was dark colored, alkaline in reaction, non-albuminous, but contained about twenty per cent. of blood. The microscopic field was full of blood corpuscles. He suffers now from a tertian type of fever, and was treated last spring for malarial fever. Next day we found on examination a moderate amount of splenic enlargement. The urine was examined two or three times, and the blood diminished in quantity as the febrile symptoms subsided. — September 8th. No pain, no stiffness, contour of spine normal.

We submitted him to a very thorough examination on the 19th of October with negative results.

December 28th. Epigastric pain has returned recently, and the boy is walking with spine stiff again. Four days ago the mother observed a little fullness of the spine between the scapulae, and now there is a distinct angular prominence measuring one quarter of an inch in height. A brace is applied forthwith.

January 19th. Acute synovitis of left knee with considerable fluid in the joint and the leg is held in semi-flexion. The circumference is only three quarters of an inch greater than that of its fellow. There is no extra heat, and very little tenderness; motion is easily made, and the distention of the synovial sac is demonstrated when the leg is acutely flexed. He complains a little of pain in the right knee. The left is enveloped in cotton wool, and the joint is put at rest in an apparatus. 25th. Marked distention of synovial sac of right knee. 27th. Admitted to the hospital, placed in a rolling chair, knees put up in straight splints, and the effusion disappeared within a month. The functions of the joints were unimpaired, and the synovitis has not recurred. He is still under observation for the spinal caries, recovery from the knee and ankle diseases having long since been well established.

## THE STUDY OF ANATOMY IN THE LEIPZIG UNIVERSITY.

BY GEORGE L. WALTON, M. D.

One of the advantages of German medical education is the thoroughness of the preliminary training. Two years at least are spent in the study of anatomy, human and comparative, physiology, physics, and botany, at the end of which period the student comes up for his *Tentamen Physicum*, familiarly called "Physicum," which is an examination in these branches. Before passing this examination his title is *Studiosus Medicinæ*; after passing it he is commonly addressed as "Herr Candidat," though the title *Candidatus Medicinæ* is not officially conferred until he has enrolled himself as a candidate for the *Staats Examen*, which he does two years later. The final examinations include, again, physiology and anatomy, so that these studies are not allowed to slip from the mind, as they are apt to do to a certain extent when the student feels that they are already credited to his account.

On the admirable opportunity for the study of physiology here I need not dwell. That the laboratory of Professor Ludwig offers the best possible chance for original investigation is well known, and I count the hours spent under this great master as among the most valuable as well as pleasant of my life. My present intention is, however, to detail the course of instruction in anatomy, through which the regular student must pass, as typical of the thoroughness with which the groundwork is laid in Germany in the purely scientific part of medical study.

A knowledge of anatomy is required for the final examination such as no amount of book cramming will give, as may be seen from the fact that one of the tests at the last "Staats Examen" was to dissect the sphenopalatine ganglion and its branches. To this Staats Examen, which must be passed before a license is granted to practice in Germany, no one is admitted who has not previously passed his Physicum; it is also expected that he has spent at least two terms in continuous dissection; that is, every day a half day, presenting his work for inspection. It is expected that twelve parts will be dissected by each man: a head, upper and lower extremity for muscles, the same for blood-vessels, and the same for nerves. Besides this, each is expected to have dissected at least once a brain and the thoracic and abdominal viscera. Not all of the students come up to this expectation, especially in nerves, but if not it is at their own risk, as they are liable to be called on to dissect any portion of the body as a part of the final examination.

The Anatomical Institute is under the direction of Professor His, his duties being shared by Professor Braune. Both of these are names familiar to the medical world, the former in America principally through embryological and histological investigations, the latter more recently through his anatomical plates. The building, which is of brick, the main division two stories high, is approximately in the form of a hollow square, two hundred and fifty feet long by two hundred deep. Its form enables the greatest possible amount of light to be secured. A broad passage way runs around three sides of the building, along the walls of which are arranged closets for the clothes of the two hundred men generally working at once in the dissecting rooms.

On the first floor of the front of the building are

the work rooms of Professor Braune, the working and living rooms of the prosector, Dr. Altmann, and the rooms of the assistants who prepare dissections for the lectures and assist in directing the students. In this part is also a portion of the museum, and a room for histological work. On one corner, and occupying the whole height of the building, is the large auditorium, which is furnished with two powerful electric lamps. Adjoining the auditorium is a room into which the preparations are brought before the lectures, dissections being wheeled in from the various preparing rooms on tables constructed for the purpose.

Nearly the whole rear lower floor is taken up by the dissecting rooms, one capable of accommodating one hundred and fifty men, two fifty each, and three smaller ones. They are excellently lighted by large windows, and contain boxes for the use of the students; also instruments, bones, and plaster casts. The instruments include vises, saws, mallets, and chisels in forms to meet all possible requirements.

In the upper floor is the laboratory of Professor His, the photographing rooms formerly presided over by Hönigkel, whose work has a wide reputation, and the work room of the mechanic of the Institute. The larger museum is also in this part of the building.

The basement is occupied by the families of the mechanic, junior, and other employees, which include a fireman, two men servants, and one who ranks higher, and whose anatomical knowledge and mechanical skill make him indispensable to the professors, for instance, in the way of making fine preparations for the class. In the basement are also the rooms in which the subjects are injected and kept. In the other parts of the building are rooms for various purposes, of which a detailed description is unnecessary.

The anatomical lectures occupy about three hours a day in winter and two in summer, the different branches being divided between the two professors. In a general way the winter term is spent more on macroscopical anatomy, and the summer term on embryology and histology. It is superfluous to mention that the lectures are amply illustrated with preparations, fresh and preserved, models, etc. Professor His is a wonderful draughtsman, and his pictures on the blackboard, in colored chalks, if accurately copied, would furnish an elegant set of plates for an anatomical work.

Another means of illustration used in the lectures is the new projecting apparatus from Basel, by which photographs of microscopical sections are thrown on a large screen.

There is also abundant opportunity for the study of normal histology, both on preparations previously made, and by the making of new ones, there being not only courses in this branch in the Anatomical Institute, but in the histological department of the Physiological Institute under Dr. Gangle. In these courses every possible facility is furnished for the student to attain proficiency in histological technique in all its branches.

Embryology is not neglected, and opportunity is offered by lecture and demonstration to become thoroughly familiar with this subject, which is the special province of Professor His.

The feature of the Institute which is the most striking to an American is the amount of time spent in dissecting, and the facilities for the work. Material is abundant, the principal source of supply being the criminals and suicides. The subjects for muscle prepa-

ration are injected with a mixture of carbolic acid, alcohol, glycerine, and water. Those for the dissection of blood-vessels are first injected with a weaker solution of the same, after which the arteries are filled with a mixture of wax and sulphate of mercury. The subjects for nerve preparation are laid at once in a forty-five per cent. solution of alcohol. During the process of dissection it is the duty of the attendants to place the parts for the night in tanks where they are soaked in alcohol and covered with cloths.

The larger dissecting room is used exclusively for the preparation of muscles and articulations, and is under the charge of Professor Braune, who, with two assistants, spends the morning examining the dissections and giving aid. The students work almost exclusively in the morning, but the rooms are open from early morning till six at night. The subjects having been prepared as described, and being kept well covered and moistened by the servants while on the tables, last indefinitely, and the time spent on a part ranges from six weeks to two months.

No one is allowed to begin on blood-vessels or nerves who has not completed the muscles. With regard to the technique of muscle dissection here, one notices that the skin is first separated from the panniculus adiposus instead of the muscle being at once dissected down upon. This is, of course, advantageous when time does not come into consideration. The other dissecting rooms, that is, the three generally in use, are devoted to the blood-vessels and nerves, and are under the special charge of Professor His, who, with the prosector, spends the morning in this department, the nerves coming almost exclusively under the direction of the former. That this part of the work is thoroughly done I can testify, having dissected the whole nervous system under his direction, which occupied several hours every day for five months. The most accurate work is exacted, and no advance is allowed till all preceding work approaches in every respect his ideal of what a dissection should be, and any deviation from instructions is discouraged. In this way every nerve and every anastomosis, if practicable, is reached according to a definite plan, and the nicety with which it is prepared is only limited by the skill of the student. While working in this department each man is given a hardened brain, which the professor goes over with him privately, demonstrating every part and showing the best way of exposing it.

A minor convenience worthy of note is the opportunity for the daily sharpening of instruments on the payment of about fifty cents a term, the work being done by a man employed for the express purpose.

## RECENT PROGRESS IN DERMATOLOGY.

BY GEORGE H. TILDEN, M. D.

### PITYRIASIS ROSEA (GIBERT); PITYRIASIS MACULATA ET CIRCINATA (BAZIN).

FIVE cases of this disease, for which he proposes the name of "*rosola furfuracea herpeticiformis*," are reported and commented upon by Dr. Ichendorf.<sup>1</sup> As a rule, first, upon the neck, appear round or oval spots, the size of a pin's head, of a pea, or of a bean, of a rose-red color, raised slightly above the level of the

<sup>1</sup> Berliner klinische Wochenschrift, 1881, Nos. 33, 39, pages 552, 569.

surrounding skin, and covered with adherent, fine, dust-like scales of epidermis. The eruption at the outset is accompanied by intense itching. The favorite location of these spots is upon the neck and shoulders, and in the infra- and supra-clavicular regions. Less numerous upon other parts of the body and upon the extremities, they do not appear upon the scalp, face, hands, or feet. In a short time, usually two to three days, these spots undergo characteristic changes. They either become pale in their whole extent, subside to the level of the skin, and disappear, leaving behind a faintly marked pigmentation, or else they spread peripherically, at the same time undergoing retrograde metamorphosis in the centre. In this way ensue rings and curves which surround slightly pigmented, but otherwise normal, portions of skin. By reason of the meeting of several such rings and curves may be formed serpentine and map-like figures such as are seen in some cases of psoriasis and syphilis. The duration of a simultaneous group of these spots is about eight to ten days, but the successive appearances of new lesions extends the course of the disease as a whole to from four to eight weeks. The course of the disease is strongly suggestive of a parasitic origin. The author does not either deny or affirm this possibility, but is decidedly of opinion that the disease is not caused by *tinea trichophytans* for the reasons that it does not attack the scalp, face, or hands, regions particularly obnoxious to the invasion of *tinea trichophytans*, that it is not contagious, and that on microscopical examination no parasite could be detected.

Since writing the above Dr. Behrend has learned from Besnier, of Paris, that he (Besnier) has discovered a fungus in this disease, situated in the deeper epidermal layers, and difficult of demonstration. The spores resemble in size those of *microsporon furfur*, are scattered about, and not gathered into groups like the spores of the latter, while mycelia are few in number, and, as a rule, of large diameter.

#### PITYRIASIS CIRCINÉ ET MARGINÉ.

Under this name Vidal<sup>1</sup> describes a disease remarkably like the above. It is characterized by the appearance, first, as a rule, upon the body, but sometimes first upon the arms and thighs, of small, round, or oval, rose-colored spots, slightly elevated above the level of the skin. Their surface is dry, and by friction is caused a furfuraceous desquamation. They are of slow growth, reaching in a month the size of a franc piece. They undergo retrograde metamorphosis in the centre, and extend peripherically, forming rose-colored or yellowish-red rings in a state of desquamation. In the axillæ and inguinal regions they may become confluent, thus presenting plaques with a sharply defined border. Further development of this condition of things leads to a form of *eczema marginatum* of Hebra. They are easily cured by almost any antiparasitic treatment, but without treatment last for three or four months. On microscopical examination of epithelial scrapings from such spots is found a fungus with the following characteristics:—

(1.) Small spores of an average diameter of .001 millimetre. Many spores are smaller than this and some larger, .002 to .003 millimetre, this variation in size suggesting the name given to them by Vidal of *microsporon anomæon* or *dispar*.

(2.) Their arrangement in the form of a circle around the individual epithelial cells.

(3.) The rarity of their disposition in chains.

(4.) The absence of mycelium.

They occupy the upper layers of the epidermis, and are to be found also in the hair follicles of the face, beard, and neck. The hairs are not altered, nor is there any follicular inflammation set up by their presence. All attempts at inoculation of the disease failed, and it does not appear to be contagious.

#### VACCINAL SKIN ERUPTIONS.

Dr. Behrend<sup>2</sup> divides these into two classes. The local, which starts from the point of vaccinal inoculation and remains confined to the immediate neighborhood of the same, or else spreads from this point over a greater or less extent of skin. In this class are included erythema, erysipelas, and eczema, the last of which is especially apt to become chronic and difficult of management. The second or general class comprises various forms of skin eruption which, with or without febrile symptoms, appear at regions of the body distant from the point of inoculation and run an acute course. The second class is rare, Dr. Behrend having met with but six examples among three hundred consecutive cases of vaccination. The most common variety of the second class, and the only one hitherto described, is the so-called roseola vaccinia, mentioned by Hebra, as appearing from the third to the eighteenth day after vaccination, starting from the point of inoculation, from there spreading over the body, and regarded by him as a lymphangitis of the skin. In the two cases seen by the author, the eruption consisted in an exanthem resembling that of measles, appearing over the whole body, but less marked upon the extremities and sparing entirely the face. It appeared upon the eighth day after vaccination, and lasted two days. Besides the above variety, four others were observed by the author.

(1.) Urticarial eruption coming on the day after vaccination, and lasting a few days. This upon the mother's statement; when the case was seen the eruption had entirely disappeared.

(2.) An erythematous process resembling exactly in appearance and course the lesions of erythema exudativum multiforme. This appeared the second day after vaccination, first upon the dorsal surfaces of the hands and feet, and from there extended over the body.

(3.) Vesicular eruption of a mixed character, resembling at one spot herpes, at another vesicular eczema. This appeared first upon the arm the day after vaccination, and spread over the body in successive crops.

(4.) Bullous form, appearing first upon the face the evening of the day of vaccination, afterward upon the body and lasting some days.

For the reasons, first, the varied forms of these eruptions, second, the fact that two distinct periods of appearance are obvious, namely, one within three days after, and the other upon the eighth day after, vaccination, and third, the resemblance in character of these eruptions, to those sometimes caused by the ingestion of various drugs; the author is of opinion that the second or general class of vaccinal eruption is due, not to any specific action of vaccine virus, but rather to the introduction of foreign material into the blood. In the case of those eruptions which appear during the

<sup>1</sup> Annales de Dermatologie et de Syph., 2me série, 1882, No. 1, page 22.

<sup>2</sup> Berliner klinische Wochenschrift, 1881, No. 46, page 679.

first period, this foreign material is the vaccine matter itself. In those eruptions which appear during the second period, and which correspond in point of time with the beginning of suppuration at the point of inoculation, the aetiological factor is the absorption of the products of such suppuration. The existence of the "vaccine généralisée" of the French authors is denied, the inoculability of such eruptions not having been demonstrated.

#### BACILLE LEPROÛ.

Cornil and Suchard<sup>1</sup> having made microscopical examination of several specimens taken from cases of tuberculous leprosy, report as follows. The tubercles in the skin consist of an infiltration into the papillary and dermal layers of the same, of large globular cells, spheroidal or slightly flattened in shape, very numerous and situated between the fibres of the connective tissue. The papillae of the skin are not clearly marked at the level of the centre of the tubercle, and both glands and hair follicles are atrophied and destroyed. The epidermal layers are thinned to such a degree, that the surface of tubercles not yet in a state of ulceration is devoid of hair. Specimens taken in the fresh state, from the living patient and teased in water, showed in the fluid separating the elements of tissue spherical grains and rods possessed of spontaneous movements. These rods bend and turn themselves. In order to obtain sections small bits of skin, excised from the living patient, were placed first in alcohol of 40°, and then in absolute alcohol. The sections made from these were colored in a solution of methylaniline 5 B, one part to five of water, then washed successively in a solution of carbonate of soda, one part to four of water, and in absolute alcohol. Finally, they were treated with oil of cloves and put up in Canada balsam. By washing in alcohol some of the coloring matter is removed from the protoplasm of the cells, and it is necessary to discontinue its action before the bacterial rods themselves are discolored. In successful preparations all the cells composing the special infiltration of leprosy are to be seen filled with numerous rods, which are colored of an intense blue. The cell protoplasm is of a blue tint merely, while the fibres of the connective tissue are uncolored. These rods are rigid, immovable, an effect probably due to the action of alcohol. Some are separate, isolated; others gathered into bundles. There are but few rods to be seen outside of the cells. No bacteria are to be found in the various layers of the epidermis, the inference being that the epidermis is impenetrable to these bacteria. Bacteria were also found in various internal organs, notably in the liver of one case, which liver also presented the appearances of hypertrophic cirrhosis.

#### LEPROSY.

The following conclusions with regard to the bacterial nature of this disease are given by Dr. Albert Neisser:<sup>2</sup>—

(1.) Leprosy is a true bacterial disease caused by a special variety of bacteria.

(2.) These bacteria enter the organism as such, or, more likely, as spores, and remain in a state of incubation in certain depots, the lymphatic glands, perhaps, for a longer or shorter period of time. The term of incubation of these bacteria varies greatly, not only as

compared with the incubation stages of other infectious diseases, but also in different cases of leprosy.

(3.) From the above-mentioned depots the disease spreads in the body, principally in the skin (lepra tuberosa), and notably in those regions exposed to insult, the face, hands, elbows, and knees, and also in the peripheral nerves (lepra anæsthetica). Other parts of the body, testicles, spleen, cornea, cartilages, and liver are less subject to invasion.

(4.) The bacteria or spores give rise to inflammatory processes in organs or parts of the body which are supplied with blood-vessels, but in those parts where there are no blood-vessels to immigrations (Eiuwanderungen) of cells from the periphery inwards. The lymphatic cells containing spores or bacteria constitute the material of which the special neoplasms of leprosy are made up. The specific action of these bacteria transform the ordinary wandering cell into the specific cell of leprosy, the shape, course, and disappearance of which are characteristic.

(5.) Leprosy is probably an infectious disease, and its specific products are contagious. The disease is not only directly contagious, but also indirectly so, its specific bacteria or germs being transferred by various objects.

(6.) Leprosy is not hereditary.

(To be concluded.)

### Hospital Practice and Clinical Memoranda.

#### TWO SUCCESSFUL CASES OF OVARICTOMY; MARKED DISCREPANCY IN AGES; REMARKABLE SIMILARITY IN HISTORY AND FORM OF DISEASE.

BY GEO. H. BIXBY, M. D.

*Surgeon to St. Elizabeth Hospital for Women; Gynecologist to the Carney Hospital.*

CASE 1. December 5, 1881, I was requested by Dr. Henry I. Bowditch to see a patient with him in his office who was suffering from great distention of the abdomen. In order to insure a thorough examination, she was advised to enter the Carney Hospital. Two days later, at the hospital, the following history was elicited. Miss D., aged fifty-seven, native of Maine, is of long-lived parentage. The father, whom she resembles, lived to the age of ninety. The mother died of phthisis.

*History of Menstruation.*—First appearance at sixteen in normal type; at seventeen she suddenly became stout but very anæmic, and the menses failed to appear for three successive months. A vigorous tonic treatment in the course of time was followed by a dissipation of the unnatural flesh, the return of the menses, and a complete restoration of the general health. Menstruated like ever after and the climacteric at forty-nine were free from complication. Since her thirtieth year she has lived in the extreme West. There she had typhoid and later intermittent fever. For some years past she has resided in the territory of Montana.

At the age of forty-two, on one occasion while bathing, her attention was suddenly directed to a firm smooth growth in the left ovarian region, the size of the palm of the hand. She paid no attention to it, and a few weeks later was unable to find it. In her fifty-fifth year the abdomen commenced gradually to enlarge, and eight months later, materially interfered with respiration and locomotion.

<sup>1</sup> Annales de Dermat. et de Syph., 2me série, Tome II, No. 4, page 654.

<sup>2</sup> Virchow's Archiv, Band 88, 4, No. 3.

The case was correctly diagnosed by her family physician, Dr. Chalmers, of Ogden, who advised her to return home and seek relief.

November 15th she left Montana for Boston, arriving on the 28th, having traveled thirteen days in coaches and steam cars without reclining. During this extraordinary journey she partook of only three full meals. This abstinence was necessary in order to control the constant tendency to emesis, caused by the upward pressure of the enormously distended abdomen. Her diet consisted of tea, milk, and fruit. Notwithstanding this remarkable experience, she arrived in Boston a little fatigued, but without injury. At present, a week after her arrival, having fully recuperated, she seems to be in the enjoyment of excellent general health.

*Inspection.*—The patient is a brunette, above the average stature, with prominent features, a countenance suggestive of firmness, endurance, and a wiry temperament. There is general emaciation, especially of the chest and superior extremities. Abdomen largely distended.

*Palpation.*—Girth of abdomen at umbilicus, forty-one inches.

Percussion elicits universal dullness anteriorly, of which the wave is unbroken. Clearness in both flanks, and a solid mass in left ovarian region, size of a fetal head.

*Diagnosis:* Cystic degeneration of the left ovary.

Dr. Gilman Kimball, of Lowell, kindly examined the case, and confirmed my views. An operation was advised, and at once accepted. From the foregoing history I felt justified in predicting a favorable prognosis.

January 16th. Four weeks and two days since her departure from Montana, eighteen days after her arrival, one week in hospital, without any special preparation except an enema the night before, and also half an hour previous to the operation, in the presence of Dr. G. Kimball, of Lowell, Drs. Henry I. Bowditch, Lyman, Weston, Bundy, Woodworth, of Boston, with the assistance of Dr. Bundy, Messrs. Boutwell and C. W. Sparhawk, internes of the hospital, and members of the Harvard Medical School, the operation was undertaken under strict antiseptic precautions. Strength of spray one to sixty. The latest modification of Crosby bed, furnished me by Messrs. Codman and Shurtleff, was employed as an operating table. Length of incision six inches. There were slight adhesions anteriorly, apparently recent. The tumor consisted of a large central monocyst, inclosing a solid multilocular mass in left ovarian region.

The pedicle of medium length, was transfixed with a needle armed with ligature of stout English braided silk, each part tied separately, the ligatures passed around the whole, and with much force tied a second time. The wound closed with seven silver sutures, was antiseptically dressed, and the patient left indefinitely, as is my custom, on the operating bed. Weight of cyst and contents seventy pounds.

*Subsequent History.*—Briefly: from first to sixth day average pulse 100; temperature 99° F. From sixth to tenth day, pulse 100, temperature 98°. From tenth, and after, normal pulse and temperature.

The following points are worthy of separate mention:

(1.) Urine voided voluntarily from choice from the first day.

(2.) Fourth day, natural and painless dejections, and ever after with occasional aid of enema.

(3.) Seventh day, removal of stitches; wound healed by first intention.

(4.) Fourteenth day, removed from operating bed and room. The change might have been made as early as the eighth day.

(5.) Sat up two hours without discomfort on the nineteenth, walked about her apartment on the twenty-first, discharged on the twenty-fourth day.

**CASE II.** Miss F., aged twenty-eight, native of New Bedford, consulted me December 28, 1881, for an enlargement of the abdomen. Her father and sister died of phthisis. Her mother, whom she resembles, still lives in the enjoyment of good health. Since her fifteenth year she has worked more or less in a cotton factory, a form of labor requiring more or less lifting. The catamenia first appeared at sixteen in normal type, three to four days' duration. The function continued normal, and her health was excellent until the twenty-second year, when, no doubt from overwork and confinement in the vitiated atmosphere of the mill, she became debilitated, anæmic, and generally bloated. The menses failed to appear for eight weeks. After a few weeks of tonic treatment her health commenced to improve, and in due time the catamenia returned, and she was fully restored to health. This favorable condition of affairs continued three years and a half. In her twenty-sixth year the menstrual interval was reduced to two weeks. In the autumn of 1880 the abdomen commenced to enlarge gradually until June, 1881, when the distention was so great as to interfere with both respiration and locomotion. About this time her family physician, Dr. Geo. D. Hough, of New Bedford, pronounced the case ovarian, tapped, and entirely emptied the cyst.

The beneficial result was soon manifest by improved appetite and digestion, a return of the interval of menstruation to normal, and a corresponding effect upon the general health.

The tumor gradually refilled. At present the abdomen is distended to its utmost capacity.

*Inspection.*—The patient is a blonde, below the average stature, with unusually bright and cheerful countenance. There is general emaciation; palpation; girth of abdomen at umbilicus thirty-six inches; percussion elicited dullness anteriorly, with signs of fluctuation with an unbroken wave. In the left ovarian region a smooth, solid mass, the size of a fist, is easily felt. *Diagnosis.* cystic degeneration of the left ovary. Operation advised.

The operation was appointed for the 3d, but had to be postponed one week. If the calculation were accurate, this would bring the next menstruation to within less than a week of the operation. As her condition would admit of no further delay, this fact was not considered a bar to immediate operative procedure. Accordingly, January 10th, without any special preparation, save a laxative the night before, and an enema the morning of the operation, in the presence of Drs. Kimball, of Lowell, S. G. Dearborn, of Nashua, N. H., Bundy, Weston, Woodworth, and Doble, of Boston, and Mr. H. W. Boutwell, interne at the hospital, of the Harvard Medical School, the operation was undertaken under strict antiseptic precautions. Strength of spray, one to sixty. Length of incision five inches. There were no adhesions. The tumor consisted of a central monocyst, with semi-solid mass inclosed, the latter situated in the left ovarian region. Weight of tumor fifty pounds. The pedicle, of medium

length, was unusually broad, and with the subjacent tissue, uterus, etc., presented unusual vascularity. An attempt was made to enucleate a portion or all of it, but was abandoned on account of the hemorrhage which followed before proceeding very far, but enough had been done to convert the original pedicle into two distinct portions, each of which was transfixed, separately ligated, seared with black, hot canterbury iron, and dropped. The wound was closed with seven silver sutures, and dressed antiseptically, and the patient, like the last, left indefinitely on the operating bed.

*Subsequent History.*—January 10th. Operation ended at one p. m. Shortly after recovery from effects of ether a decided tendency to nausea was controlled by vigorous fanning. Six p. m. Pulse 120; temperature 101° F.; return of nausea; partially controlled by fanning, hypodermic injection, and mustard to the epigastrium.

January 11th, nine a. m. Nausea continued, and occasional vomiting during the night; pulse 110; temperature 100° F. Six p. m. Nausea; vomiting entirely controlled by hypodermic injection and a suppository of opium and belladonna, and absolute rest given to stomach. Thus far no nourishment by mouth. Injections of beef tea and brandy every four hours. Restless, but stomach at rest.

January 12th, nine a. m. Pulse 110; temperature 100° F. Twelve m. Pulse 120; temperature 100½° F.

January 13th, nine a. m. Pulse 128; temperature 102½° F. Twelve m. Pulse 110; temperature 101° F.; peritonitis suspected; wound and abdomen examined; no signs discovered; menses appeared; cause of rise of temperature accounted for; the catamenia continued four days, during which pulse averaged 104; temperature 99½° F.; after their cessation the pulse came down to 100, temperature 98° F.

From this time the case proceeded without complication.

*Points of Special Interest.*—(1.) Cause of vascular condition of the viscera and the sudden and extraordinary rise of temperature were no doubt owing to approach of menstruation.

(2.) An unusually abundant flow of apparently healthy urine from the first.

(3.) Natural dejections daily after sixth day.

(4.) Stitches removed on seventh day; wound found to have entirely closed by first intention.

(5.) Removed from operating bed and room on the eighth day.

(6.) Sat up on fourteenth, walked about on the sixteenth day.

(7.) Twenty-fifth day, discharged, rode fifty miles to her home.

# “UNUSUAL OR ACCIDENTAL RESULTS OF VACCINATION.”

BY MORTON PRINCE, M. D.

ATTENTION has been called in late numbers of the JOURNAL by Dr. Holt and Dr. Vincent Y. Bowditch to a form of skin eruption sometimes accompanying vaccination. Dr. Holt says: “I am well aware that no definite conclusion can be drawn from so small a number of cases, but from the facts presented I think it a reasonable presumption that this eruption was in some way brought about by vaccination. If such is the case, and this result is going to occasionally follow

vaccination with animal virus, it is highly important that the fact be known.” Having had considerable experience in this matter during the late extensive vaccinations performed under the auspices of the city, I have thought a few words detailing briefly the results of my observations would not be out of place.

Skin eruptions accompanying successful vaccinations were so frequently observed that I ceased to regard them either as “unusual” or “accidental.” In what proportion of cases they occur I have been unable to ascertain, as only a certain percentage of those vaccinated return for inspection. Though the number of such cases observed was quite numerous, I have no doubt they are relatively infrequent considering the total number vaccinated at the City Physician’s office since January 1st was more than seven thousand.

These skin eruptions derive a certain practical importance from the fact that they almost always cause alarm in the family by the suspicion that the individual has contracted small-pox from the inoculation, or that “bad matter” has been used.

The most common forms of eruption noticed were the papular or lichenoid and erythematous. I have seen several cases similar to those described by Dr. Holt.

One of the most interesting cases was that of a young girl about eighteen years of age, vaccinated for the first time, who returned for inspection on the eighth day with two typical compound vesicles. An eruption began to appear two days previously. When seen nearly the whole back, chest, and neck were of a uniform dark-red color, looking as if she had been painted. In the neighboring healthy skin were blotches of the same nature, varying in size from that of a ten cent piece to a silver dollar. There was no swelling. On the legs, where there was very little erythema, and scattered over the chest, but particularly at the circumference of the reddened skin on the neck, were numerous papules, many of them having fine vesicles, others pustules, on their summits, plainly evident to the naked eye. The constitutional disturbances were moderately severe. When seen some days later the whole eruption had disappeared.

Another case of interest was one reported to the Board of Health, and which I saw through the kindness of Dr. McCollom. It turned out to be one of urticaria, the most severe case I have ever seen.

The patient was a girl about sixteen years of age. The inoculation had resulted on the arm in typical vaccine vesicles. Nearly the whole back, nates, and thighs were covered with large wheals, which in some places were confluent, forming large, elevated patches. The intervening skin was reddened and much swollen. The constitutional symptoms were very severe.

Another similar though less severe case was also reported.

Papular eruptions were very common, and ceased to attract notice.

One moderately common phenomenon was an eruption of small pustules in the areola around the vaccine vesicle. These sometimes resembled the pustules of true small-pox, and in one case, where they were beautifully developed, were used clinically to illustrate the appearance of the small-pox eruption.

I am inclined to look upon these skin eruptions as due to nervous disturbances simply. One case was strikingly suggestive of this explanation. A young adult returned on the eighth (?) day after secondary

vaccination. The matter was introduced into the left arm in the usual place with a successful result. The skin on the back of the left fore-arm was reddened and swollen. The skin in an identical region on the right arm was in a similar condition. There was nothing to indicate in other respects erysipelas. This case reminds one of the physiological experiment of placing one hand in cold water, whereby the temperature of the other hand is also reduced. Possibly a similar sympathetic influence was at work here.

One case, I think, should be recorded as showing one of the accidents liable to occur, and against which patients should be warned.

A young girl, about six or seven years old, was successfully vaccinated. When seen at the end of a week, besides the vesicles on the arm there was another of typical appearance situated at the inner canthus of the left eye, just external to the caruncle. The conjunctiva of the lid and of the globe became later injected and swollen, as well as the neighboring parts of the cheek. The whole had an alarming appearance, but the vesicle ran through its course without doing further damage than will result from the probable distortion of the tear passage from contraction of the cicatrix. In this case the patient had without doubt accidentally inoculated herself from the virus rubbed on the arm. The date of appearance of the vesicles was about the same in the two places.

Accidental auto-inoculation is moderately common, though it is not usually in a place to do mischief. I have seen one doubtful vesicle thus produced on the inside of the nose, and another on the forehead, where it was only of consequence so far as the future scar was concerned.

Seaton<sup>1</sup> remarks that "in young children of full habit, especially in hot weather, about the ninth or tenth day, when the areola is at its height, an eruption of roseola will sometimes take place, chiefly on the extremities; sometimes the eruption has a papular form (vaccine lichen), and sometimes it is vesicular. These eruptions are generally very transitory; their ordinary duration does not extend beyond a week, and they very seldom indeed last beyond the falling of the scab."

Judging from the number of times I have been questioned by anxious parents on the meaning of these eruptions, I believe with Dr. Holt that the fact of their liability to follow vaccination should be widely known.

## MASSACHUSETTS GENERAL HOSPITAL.

SERVICE OF DR. SAMUEL CABOT.

REPORTED BY MR. F. H. LOMBARD, HOUSE OFFICER.

### COMPOUND FRACTURE OF JAW.

CASE I. November 16, 1881. C. E. T., aged thirty-eight, was kicked by a horse, the blow cutting the upper lip and left ala of nose through to the subjacent bone, separating the two superior maxillæ at the intermaxillary line and driving the alveolar process of each back upon the antrum, leaving no possible holding ground in the jaw itself for wiring the two halves together. Under ether the two middle incisors were wired. A second wire passed around the lateral

incisors was carried upwards and backwards through the alveolar process, and the two ends, brought out through the nostrils, were twisted together beneath the septum of the nose upon a bridge of gutta percha. Several stitches were taken in the nose and lip, and by means of a four-tailed bandage passed under the chin, the teeth of the lower jaw were kept in apposition with those of the upper. All swelling had subsided on the fifth day when the stitches and the wire that passed through the nose were removed.

Except for a slight, facial erysipelas lasting five days the patient did uninterruptedly well, and left the hospital on the twentieth day with firm union and showing no trace of his injury except the loss of a right upper incisor and a canine tooth which, being loose, were removed with a bit of carious jaw the day he left the hospital.

February 16, 1882. Reported to-day, three months after accident. Features natural, jaw firm, no sign of the injury except that on closing the jaw the two rows of teeth approximate perfectly, instead of the upper overlapping.

### GUNSHOT WOUND OF THIGH.

CASE II. November 29, 1881. J. M., aged 21. A minie ball from a rifle passed through the middle of the left thigh badly comminuting the femur in its passage. The patient was brought to the hospital an hour and a half after the accident. The foot was strongly everted, the leg visibly shortened. There had been considerable hæmorrhage from the wound where the ball entered the inner aspect of the thigh, but when seen by the surgeon all bleeding had stopped and both openings made by the ball were smoothly and evenly closed.

Comminution of the femur was established beyond a doubt by the presence of detached spicule of bone, one of which, somewhat larger than a cherry stone, could be felt immediately beneath the skin.

Buck's extension apparatus was applied to the leg and the wounds dressed with cloths wrung out in hot carbolic acid and water, one to forty, that were changed every three hours.

December 26th. Both wounds have closed. Dressing omitted. There has not been as much as three ounces of discharge from the wounds since the dressings were first applied. Leg in good position.

January 27, 1882. Eight weeks after injury. Apparatus removed. Firm union, — excellent position, one and a quarter inches shortening.

The patient kept up passive motion of the knee for several days, was then allowed to be about the ward on crutches, and February 8th was discharged.

The ease was remarkable from the entire absence of constitutional symptoms, there being no pain after extension was applied and the temperature never passing 99.6° F. [except for a single day after imprudent eating when it reached 104° F.].

### POPLITEAL ANEURISM.

CASE III. December 3, 1881. C. C., age forty, hostler. First noticed a small, pulsating tumor the size of a walnut in right popliteal space last April. No history of strain or injury. Tumor has doubled in size within two months; now fills the whole popliteal space, is rather larger than a goose's egg, is firm and tense; no discoloration. Pulsations are visible in the tumor

<sup>1</sup> Reynolds's System of Medicine.

itself in the course of the femoral as high as Hunter's canal, and in the integument covering the upper third of calf of leg. General health good, heart normal, pulse can be felt in both tibials. Worked regularly up to time of entering hospital. Seeks advice because of recent increase in amount of pain and throbbing.

December 5th. Was etherized at three P. M. When fairly anesthetized the tourniquet was applied over the femoral one and a half inches below Poupert's ligament until pulsation in the aneurism had ceased and a second tourniquet was placed in readiness for application in the course of the vessel about three inches lower down.

Pressure was thus made alternately at these spots for ten hours, the tourniquet being changed every hour. At the end of ten hours all compression was removed and the patient allowed to recover from his ether sufficiently to answer questions. Absolutely no pulsation could be felt in the tumor. After an interval of an hour, upon deep pressure, pulsation was felt at the point where the current entered the sac. Ether was again given, the tourniquets reapplied and continuous pressure again maintained for five hours. The tourniquets were then removed and the patient allowed to come out from his ether. The tumor had ceased to pulsate and was reduced more than one third in size.

During etherization the temperature, pulse, and respiration were recorded every hour, and averaged respectively, temperature 99.2° F.; pulse 86; respiration 28. The patient received during the time he was under ether enemata containing beef tea three and a half ounces, brandy four and a half ounces, milk two ounces.

With the exception of slight headache and a sensation of numbness in the calf and foot there were no discomforting after effects from the prolonged etherization and pressure.

The patient was kept in bed for eight days, at the end of which time he was removed in the ambulance to his home, the tumor being reduced to the size of an English walnut and no return of pulsation.

February 29, 1882. Eleven weeks after the operation. There is no return of pulsation in the tumor which has not shrunk perceptibly since last report. Patient has resumed work.

#### SPASMS OF MUSCLES OF NECK.

CASE IV. October 6, 1881. F. E. M., age twenty-nine, type-setter. Family and personal history exceptionally good. Physique better than the average. April 28, 1878, after six months of uninterrupted work at setting type in an over-heated, low-studded room, by an open window, averaging ten and frequently passing fourteen hours at his post, the patient was seized with muscular twitchings of the head and neck, the chin being jerked violently toward the *right* shoulder and oscillating between that point and the median line, where it was impossible to keep it.

Kept at his work for several days, but at the end of a week the twitchings had become so violent that he was scarcely able to stand. Sought medical assistance, tried countless local and internal remedies, but with no relief until the middle of June (six weeks) when morphia was administered subcutaneously with immediate relief. Continued to take large doses daily for a month, and on the 1st of August resumed work, being able, with the assistance of a strap passed under left axilla and around the forehead, to set type nearly as well as ever.

Improving gradually he was able to abandon the strap the 1st of January.

Duration of this first attack nine months. Then followed an interval of twelve months (January, 1879, to January, 1880), during which the patient was as well as ever except for a slight difficulty in turning the head to the left.

In January, 1880, was seized again, the head this time "veering gently but firmly to the *left* and remaining there persistently." Worked for eight weeks wearing a strap, the symptoms increasing in severity until, at their maximum, the head twitched violently from side to side at the rate of forty oscillations a minute for sixteen hours. Had recourse again to subcutaneous injections of morphia, began to improve about the 1st of May, and the 10th of June resumed work, feeling freer from all symptoms than at any time since the first attack. This immunity, however, was of short duration. In three weeks he was seized suddenly again, and from that time (July 4, 1880) until now he has never been entirely free.

Entered hospital October 6, 1881. Three months previous there was a sudden increase in the severity of the spasms, the chin being drawn violently toward the *right* shoulder. A few weeks later it was drawn with equal force to the *left* side, and the tendency has been in this direction ever since. There is marked rigidity of the right sterno-mastoid. Any effort to bring the chin into the median line causes painful muscular twitchings confined to the head and neck. At intervals lasting from a few minutes to several hours the head jerks violently from side to side, these movements being entirely beyond the control of the patient.

The galvanic current was applied daily to the right sterno-mastoid with slight relief in severity of spasms at the end of six weeks.

Intra-muscular injection of the sulphate of atropia in doses of one sixtieth of a grain, and of curare one third of a grain, the application of cantharidal collodion and of the tincture of calabar bean to the affected muscles, and ice to the spine, were all tried in turn without effect, except in the case of calabar bean which produced temporary relief for an hour or two after application.

The question of cutting down upon and stretching the spinal accessory nerve at its point of distribution to the affected muscles was entertained but deemed inadvisable till milder measures should have failed.

At the suggestion of Dr. A. T. Cabot it was resolved to try the effect of fixation in a plaster bandage in the manner described by Delore in the *Gazette Hebdomadaire* for March 22, 1878. The good effect of this apparatus in tonic spasm of the muscles of the neck encouraged the hope that it would be equally efficacious in controlling the clonic spasms of our patient.

The head was accordingly held with the chin pointed somewhat away from the side towards which it tended to be drawn, and the head and shoulders were then enveloped in a plaster bandage.

No inconvenience was experienced from wearing the casque after the first few days. On the contrary the patient expressed intense relief from the total cessation of the muscular twitchings which were now rendered impossible. This apparatus was worn for eight weeks, the patient resuming his work at long hours without experiencing any return of his trouble.

On removing the casque at the end of eight weeks the muscles were found to have lost their rigidity and to have regained their normal softness. For seven

days there was no return of the spasms, and the patient was able to maintain the chin in the median line or turn it to either side without any effort or pain. At the end of a week there appeared slight symptoms of returning trouble, and at his request a second casque of plaster-of-Paris was applied.

In the mean time a plaster cast of the head and neck was taken, upon which an apparatus of thick leather has been moulded that hinges at the back of the neck and laces over the forehead and chin, is light and readily applied. Wearing this while at work so long as there is any tendency to spasmodic action, it is fair to presume that the patient can be in time permanently cured.

## Reports of Societies.

### PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

#### SECTION OF MATERIA MEDICA AND CHEMISTRY.

FRANCIS H. WILLIAMS, M. D., SECRETARY.

MARCH 1, 1882. DR. ROBERT AMORY presiding. DR. E. G. CUTLER read a paper on

#### OXALURIA AND THE MICROSCOPIC EXAMINATION OF URINARY SEDIMENTS.

After citing cases illustrative of the various conditions under which the crystals of oxalate of lime appear in the urine and indicating their proper treatment, he said that the glasses ordinarily employed for the collection of sediments were of faulty shape in being conical and not having parallel sides. The specific gravity of the constituents of the sediment did not usually vary much from that of the urine, and they very nearly floated in it, so that unless the conical glass were occasionally agitated to shake down the matters to be examined they might well remain, touching the sides of the glass at any point. With a large amount of urine he used a glass with parallel sides, holding half a litre, advised by Professor Wood, of the Harvard Medical School. With small amounts he made use of an old burette of one hundred cubic centimetres' capacity, held upright in a clamp; and with very small amounts a large pipette with a bit of wax on the end. He laid out thirty or more slides, and filled a pipette from all the layers of the sediment, beginning at the top. This was then emptied on the slides, guttatum, in regular order, and a second pipette was filled by sinking it from the surface of the urine to the top of the sediment, thus getting a portion from each layer of the specimen. These slides were then arranged in regular order, and examined from the bottom of the series upward. On a paper was recorded everything found, which, if the above method were strictly adhered to, would at the same time represent the relative quantity of the constituents of the sediment.

The urine should be allowed to stand not less than six nor more than twelve hours before the examination. A magnifying power of not more than three hundred and fifty diameters was to be used, and the light should be daylight. Where an abundant deposit of urates obscured the field a pipette of sediment was added to a test tube filled with warm water, when, after standing a few hours, was subsequently examined.

To bring out casts for demonstration or in artificial light he used a one per cent. solution of methyl-green

or a two per cent. solution of methyl-aniline, or Beale's iodine solution, a drop of which was either added to the urine on the slide, or a small quantity mixed with it before settling.

In an attack of bronchitis, typhoid fever, erysipelas, or in fact in any disease where the temperature reached 102° F., or after a debauch, he had hardly ever failed to find hyaline casts of narrow diameter in the urine on careful search.

DR. B. F. DAVENPORT offered a communication upon the

#### OLD AND NEW PHARMACOPEIAS.

The earliest known American work upon pharmacy is a tract written by the Rev. Thomas Harward in 1732.

Previous to the Revolution, and for over twenty years afterwards, the evils of irregularity and uncertainty in the preparations of medicines was felt with a peculiar weight from the absence of any recognized national standard, there being a number of pharmacopœias, and of dispensaries founded thereon, which were in common use in different parts of the country. These were, however, commonly some one of the three British, that is, the London, Edinburgh, or Dublin Pharmacopœia. On October 3, 1805, the Massachusetts Medical Society voted to prepare a Pharmacopœia better adapted to the needs of the American physician and apothecary. So they published theirs, the first American Pharmacopœia, in 1808. It says: "As there frequently arise errors of no small importance from the promiscuous use of weights and measures, it is proper that the quantities of substances, whether fluid or solid, be determined by weight." Some of the formulæ are expressed in terms of parts by weight instead of in specified weights, thus in these two particulars anticipating by as many years the new edition of the United States Pharmacopœia soon to be published. The general plan followed in this first American Pharmacopœia was that of the then recent edition of the Edinburgh Pharmacopœia. The Massachusetts Medical Society sent copies of its Pharmacopœia to all the different State medical societies, with a circular letter requesting criticism of their work, and expressing a desire that some means might be devised to establish a standard Pharmacopœia for the United States.<sup>1</sup> In 1810 Dr. James Thacher published his commentary thereon under the title of *The American Medical Dispensatory*. The next American Pharmacopœia published was that of the New York Hospital in 1816. These two earliest of American Pharmacopœias exerted a limited influence within their several sections; but throughout the United States generally the practice of pharmacy was exceedingly unsettled, varying not only in the different sections of the country but even in the same neighborhood, and guided by no other common principle than a vague dependence upon the frequently conflicting authority of the British colleges. The disadvantages of such a condition of things at length became so obvious, and were so generally felt, that in January, 1817, Dr. Spalding submitted to the New York County Medical Society a project for the formation of a National Pharmacopœia under the authority of all of the medical societies and medical colleges in the United States. This plan met with almost universal approbation, and the general convention, held

<sup>1</sup> Medical Communications of the Massachusetts Medical Society, vol. ii., page 266.

on January 1, 1820, at Washington, D. C., published through their committee, in December of that same year, theirs, the first Pharmacopœia of the United States. This plan provided for the regular revision of the Pharmacopœia each ten years by a convention to be held at Washington, by delegates elected by the Northern, Middle, Southern, and Western sections of the country. This Pharmacopœia of 1820 was supplemented by the commentary of Dr. Jacob Bigelow, of Boston, in 1822, called Bigelow's Sequel. In 1830 those delegates who held formal writs of their election from the president of the former convention, by general concurrence decided to hold their meeting in New York city instead of at Washington, as provided for by the previous convention, while other delegates for societies and colleges in the Middle and Southern States met in convention at Washington, the regularly appointed place. These two conventions resulted in the publication of the two rival editions of the United States Pharmacopœia of 1830, the one published at New York and the other at Philadelphia, while the Pharmacopœia of 1820 had been published at Boston. In the contest for authority the Pharmacopœia published at Philadelphia gained the ascendancy, having been supplemented by the commentary published by Drs. Wood and Baché in 1833 under the title of the United States Dispensary. All the subsequent revisions have thus far been published at Philadelphia, and have been supplemented by editions of the United States Dispensary. All conventions have since been held at Washington. In the revision of the edition of 1880 the assistance of the Colleges of Pharmacy was first invited, and tests for identification and for purity were first introduced. Unlike the preceding, it was in English text alone. The revisions of 1850, 1860, and 1870 have kept the United States Pharmacopœia up with the great advancements made in the pharmaceutical sciences in a quite satisfactory manner, yet the revision proposed by the convention of 1880 is to make very many more changes than ever before in the work. It is to be so much enlarged in the fullness of its details that a commentary, as heretofore, will not be absolutely necessary, although doubtless it may be very useful. The interest and participation in the work of this revision is more widely spread through the several States of our Union than ever before. The principal changes to be made are as follows: All measures of capacity to be abandoned, and quantities to be expressed in parts by weight, except that in the fluid extracts the amount of the finished product may be expressed in volume. The former division into *materia medica* and preparations is to be abolished, and all articles are to be arranged in a continuous alphabetical order. Concise description of crude drugs to be given sufficient for identification, either by external physical properties or else by their chemical. Tests for identity and purity of chemicals to be given, and also methods for quantitative determination, which will be as far as practicable by volumetric analysis. Methods of assay of opium and cinchona to be given, with the minimum percentage of total alkaloids in the latter and the minimum and maximum percentage of morphia in the former. The parts by weight of the ingredients entering into the formulae to be expressed in the simplest possible terms, and, whenever possible, in a centesimal ratio. Definite expression of weight, wherever necessary, being expressed both in metrical and apothecaries' weight. Weight of finished product to be specified, and where practical brought up to one hundred

parts. Several very important tables to be appended. This revision will involve a much greater amount of labor than ever before, yet it is now expected to publish the body of the work by the coming summer, and to follow it by a supplement of tables, etc., shortly afterwards, and thus before the expected supplement provided for on or before five years, resolved upon by the general convention at Washington in 1880.

Dr. Amory said that the new Pharmacopœia would have an important commercial influence, as by law of certain States and by act of Congress its standard will be used in assaying certain imported drugs; for example, under the old law the inspector could not admit opium containing less than nine per cent. of morphia, while the Pharmacopœia of 1860 prescribed as a standard only seven per cent.

According to recent legislation the United States Pharmacopœia standard of the strength of opium assay will be the future guide to the custom house inspector for the admission of foreign opium. According to the therapeutical standard of opium used by physicians, the morphia strength is supposed to be about sixteen per cent.; consequently, the standard of opium assay should be somewhere between fourteen per cent. and seventeen per cent. This strength is not agreed upon by the Committee of Revision, but whatever is agreed upon by it will probably be the law. As the methods of assay are somewhat faulty, the forthcoming revision will also endeavor to recommend a more accurate process, which will be the legalized method.

The Pharmacopœia will also give tests for various alkaloids, as quinia, and from this, as well as for other tests of purity of drugs, it will be indispensable to every medical man. The new Pharmacopœia is not a compilation, but represents a good deal of original work; much care and experiment has been given to the syrups and fluid extracts which have been carefully studied up, so that the medicinal strength shall be reliable. Hitherto many fluid extracts have been valueless, because they contained little if any therapeutical effects of the drug from which they were prepared.

Professor Diehl, of St. Louis, has prepared a large number of experiments calculated to prove that the fluid extracts properly represent the drug, and his work is incorporated in the new edition.

So, too, in regard to syrups, many of which on practical experience have hitherto seemed to be easily spoiled by rapid fermentation.

Professor Wall has carefully experimented with this subject, and his syrups, prepared nearly eighteen months ago, have been preserved by the committee to test their present value. The results of his work are also incorporated in the new edition.

Finally, the whole subject of chemistry of the *materia medica* has been thoroughly worked up by Professor Prescott, of Ann Arbor.

A posological table is purposely omitted, the ground being taken that it is not within the province of the apothecary to prescribe.

Many other points of importance have been considered, and as a result the forthcoming edition represents a work which is hardly a revised edition of previous editions, but proposes a new work, the text being entirely rewritten and the subjects divided by an entirely new method.

Dr. Amory hopes, upon a future meeting of the Section, to give further information upon the subject of the Pharmacopœia.

## AN INSTRUMENT FOR DETERMINING THE STRENGTH OF ALCOHOLIC SOLUTIONS.

The secretary showed a small and simple instrument, of French manufacture, for determining the strength of alcoholic solutions. It consists of a small strip of wood which is laid across the top of a tumbler or wine glass containing the solution to be tested; this acts merely as a holder for a piece of capillary tube, such as thermometers are made of, which is slid vertically through an opening in the wood until the lower end of the tube just touches the surface of the liquid. As soon as the tube touches the liquid, the latter is drawn up by capillary attraction, and the point to which it rises is read off on the scale on the tube which is graduated from 0 to 20; these numbers indicate the per cent. of alcohol. Or better, the liquid is sucked up a little way, by applying the mouth to the upper end, and allowed to run down to a point where it remains fixed.

The basis of the method is that in the same tube water is drawn up by capillary attraction very much higher than alcohol, so that when alcohol is present in the water it lessens the height to which the mixture will rise in a capillary tube.

The scale goes only as high as twenty per cent. of alcohol, but with stronger solutions a small quantity may be taken and diluted with once or twice its volume of water before testing.

By this instrument one may readily determine the per cent. of alcohol in dry wines, but not in those containing much sugar, as this acts in a way similar to alcohol.

## Recent Literature.

*The Human Ear and its Diseases; a Practical Treatise upon the Examination, Recognition, and Treatment of Affections of the Ear and Associate Parts. Prepared for the Instruction of Students and the Guidance of Physicians.* By W. H. WINSLOW, M. D., Ph. D., Oculist and Aurist to the Pittsburgh Homoeopathic Hospital, etc., etc. 8vo. Pp. 526.

A treatise well arranged, systematic, and generally well written; not at all original, but an excellent compilation of the best works of some of the best authors, characterized, however, by some peculiar pathology, and by the profound faith in the value of internal medication, and in the treatment of symptoms which seems to be the fundamental creed of the school to which the author belongs.

The author is evidently familiar with the literature of his subject, upon which he has drawn largely, but with discretion. The treatment he advises is, as a rule, judicious, and but little, if any, exception can be taken to the local and surgical treatment recommended for different diseases. We were almost tempted to say the same of his medical treatment, which is the only point in which his practice differs materially from that in general use, but fear we should be accused of actually favoring what we only regard as indifferent. If a patient with acute purulent inflammation of the tympanum is treated by moist heat to the inflamed drum membrane, by inflation of the drum cavity, and later by paracentesis when rupture does not occur, there can be no serious objection to adding hopes to the moist heat, or even a minute quantity of aconite, and if Hepar internally amuses him while the disease is running its course, well and good. Infinitely better this than poult-

icing the ear to destruction, or contenting ourselves with a little sweet oil in the meatus, which cannot do any good and may do harm.

The expression "general rheum" reminds one somewhat of the old erysipelatosus psora which used to "strike inwards," and we are, in reading the book, somewhat at a loss to define such expressions as "red-haired struma;" but there is in reality very much more to commend than to condemn, and the book is a fair exponent, in the local and surgical treatment advised, of sound otological practice, and we can only wish that the medical treatment recommended would bear the test of scientific analysis.

*A Text-Book of Physiology* By M. FOSTER. Second American Edition. By E. T. REICHERT, M. D. Henry C. Lea's Son & Co. 1881.

*Kirkes' Handbook of Physiology.* By W. MORRANT BAKER, F. R. C. S. Tenth Edition. Philadelphia: Presley Blakiston. 1881.

A second American edition of Foster's Physiology has appeared, but as it differs from the first in no essential features, we need only announce its publication. We were at one time disposed to criticise this American edition, but we are willing to confess that the liberal addition of illustrations is a great improvement on the English edition.

We welcome a new edition of Kirkes' Physiology by Dr. Baker, and recommend it most heartily to beginners in that study. In saying this we do not mean to imply that it is an elementary book. It is much more than that. It is particularly clear and intelligible in its descriptions of the mechanical functions of the body, and is not lacking in its exposition of the more difficult problems of the science of physiology. It is brought well up to date, and has been rendered more serviceable by the insertion of *headings* to the leading paragraphs of each chapter. The illustrations have been increased in number, and many of the old ones have been replaced by new, so that it is a delightful as well as an instructive book to read.

*Refraction of the Eye, its Diagnosis and the Correction of its Errors, with Chapter on Keratotomy.* By A. STANFORD MORTON, M. B., F. R. C. S., Edin. etc. Philadelphia: Presley Blakiston. 1881.

It is no easy task that the author has set himself, to compress within fifty-seven small pages so much information on the refraction of the eye and the various methods of determining it as may "enable practitioners to diagnose, and correctly estimate the value of, the phenomena indicating the state of a patient's refraction."

It is not surprising then if he has not wholly succeeded. He has attempted to give too much in the limited space at his command, and the chapter on Keratotomy, so called, would better, with the end in view, have been omitted.

In the preface the hope is expressed that the book "will make evident the necessity which exists for personally working out a large number of refraction cases in order to acquire anything like proficiency in prescribing correct glasses."

It may accomplish this object, but we must doubt if it will furnish the practitioner with sufficient knowledge to enable him to personally work out refraction properly.

# Medical and Surgical Journal.

THURSDAY, APRIL 27, 1882.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year including postage.*

*All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.* HOUGHTON, MIFFLIN AND COMPANY,

NO. 4 PARK STREET, BOSTON, MASS.

## HARVARD UNIVERSITY AND THE MEDICAL EDUCATION OF WOMEN.

At a late meeting of the Board of Overseers of Harvard University, the Board being called upon to advise whether the University should accept a sum of money, to be held until sufficient for the education of women in medicine by the University, and to be returned at the end of ten years if not so used, a committee of three was appointed to confer with the Medical Faculty in regard to its protest against legislation touching the medical education of women under the auspices of the University without consultation with it.

The Medical Faculty, in the mean time, was not slow to give expression to its views by the passage of several votes, in which sixteen out of twenty members concurred. A vote so nearly unanimous would under most circumstances have been thought sufficient, but it is rumored that, had any doubt arisen as to the sincerity of the conviction contained in the protest, the majority would have been also ready to seal its action with its official blood. The Faculty, we are glad to know, has not been called upon for so extreme a proof of sincerity.

A committee of the Faculty conveyed its views to the committee of the Overseers, who reported to the Board at the last meeting, April 12th. The report made no recommendations on the part of the committee of the Overseers, but presented the opinion of the Medical Faculty of the University upon the advisability of permitting women to enter the Medical School, which was substantially as follows: The Faculty, while making no opposition to the medical education of women in general, decidedly oppose it in the Harvard Medical School. The School, they say, was founded for the medical education of men, and has been endowed and sustained for that purpose, a purpose which would be seriously perverted if the School were changed into an institution for the education of both sexes alike. The Faculty has been trying to raise the standard of medical education, and has already made it higher than anywhere else in America. The examinations are harder, and the course of instruction is more complete and thorough, and more distinctly graded than in any other university in the country. Beginning with anatomy, the course ends in the third and fourth years with more abstruse subjects. Although the fourth year is still voluntary, an effort is being made to extend the regular course. The School and the Faculty have now all they can do, and

are doing all that the community can ask of them; and all that they are doing is directly in the line of raising the standard of medical education, and educating students to be good physicians. The addition of a mass of women to the students would probably result either in seriously deranging the machinery of the School, or the standard of the School and of medical education would have to be lowered to the capacity of the many. The closing portion of the report of the Faculty consisted of the following votes, which they adopted in several recent meetings:—

*Voted*, That if the president and Fellows have a desire to be informed of the present views of the Medical Faculty upon the question of female medical education in the University, the latter would respectfully state that, in their opinion, it is not advisable that the president and Fellows should open a course of medical study to women under the auspices of the University.

*Voted*, That the fact that the Medical Faculty is strongly adverse to undertaking female medical education would be, in their belief, of itself fatal to the success of an attempt in that direction.

*Voted*, That female medical education cannot be undertaken in the Medical School without a serious risk of detriment to the interests of the medical education now given to men.

This report having been accepted by the Board the following, which had been proposed at the last meeting, was again brought up by one of the overseers:—

*Voted*, That in the opinion of this Board, it is not advisable for the University to give any assurance, or hold out any encouragement, that it will undertake the medical education of women of Harvard College in the medical school.

After considerable debate the vote was passed by twelve to eleven, *all* the clergymen on the Board voting in the negative, and here the matter stands.

We have given our readers, as briefly as possible, a sketch of the course of recent events and recent action of the University authorities where they relate to the medical education of women, without comment of any kind, and as a result we find that the question has *apparently* accomplished an entire circle and returned to the point from which it was started, by a skillful hand, several years ago, namely: the Corporation of the University. But, though traveling in a circle, the subject has managed to receive considerable enlightenment in the course of its journey.

The Corporation ordinarily originates University legislation and sends it down to the Overseers to be acted on. In the matter of the medical education of women, either from a lack of courage on the part of the Corporation, or a desire for time on the part of the friends of the movement, the Corporation requested advice from the Overseers. This advice is now at length conveyed in a decisive form in the vote above recorded, and it is supposed that the Corporation will act thereon at its approaching meeting.

It is known that the Corporation consists of seven members; we believe the pretense of a certain graceless poet, expressed in a well-known parody, that these seven are represented by one, does not apply to the

present question at least. Of the seven members five are thought to be opposed to the medical education of women by the University, while two are thought to be in its favor. Of the five opposed one is absent from the country.

Two years ago the President of the University stated in his annual report that, "It is obvious that both the governing boards are in favor of giving medical education to women in the University under proper restrictions;" and again, "It is apparent that the reasons given by the Faculty for not admitting women to the school are temporary in their nature." At the present time we find the Medical Faculty opposed to the medical education of women by the University by a vote of sixteen to four; the Corporation — unless we are mistaken — by five to two; and the Overseers opposed to even holding out any encouragement that the University will at any *future* time undertake such education, by twelve to eleven. Had the form of the last vote been less sweeping and less prospective in its character, we have reasons for saying that the majority vote would have been much larger. It is apparent, therefore, either that the President was mistaken in the position assumed in his report two years ago, or that the medical education of women at Harvard is losing favor and friends among those bodies of the University immediately concerned in the decision of the question, — for that the Medical Faculty, as well as the governing bodies, is immediately concerned in the decision of such a question, whether we consider the strength of its expressed convictions or the overshadowing importance of its contributions to the progress and prosperity of the University's medical department, no longer admits of doubt.

A certain degree of direct interest in the management and regulation of the school under its instruction has been formally accorded the Medical Faculty of late by the passage of a vote on the part of the Corporation, that no matters relating to medical education in the University shall be acted upon, in future, until the Medical Faculty shall have had a full hearing on the subject at issue. Hitherto one single individual has enjoyed the advantage over his colleagues of being a member at once of each of the governing bodies, and of each of the school faculties of the University, — that individual being the President. Under such an arrangement, as soon as the President became a partisan upon any important subject, it was scarcely possible that a clear understanding or intelligent cooperation should be established between such a body as the Corporation and the School Faculty involved, and it became almost inevitable that the faculty should feel, with a president in opposition, that they were the victims of a principle comparable to that against which our forefathers rebelled — taxation without representation. The present controversy, between the governing bodies and the Faculty, about the medical education of women, at Harvard, as is always the case when Hector and Achilles are drawn into blows over some one else's Helen, has been long, wearisome, and marked by mistakes as well as by no little personal acrimony on both sides. The most serious mistake on the part of the Medical Faculty we consider to have

been the proposition — whether made as a bluff or in good faith — of three years ago to undertake the education of women for a money consideration of \$200,000; and the most ludicrous and fatal mistake on the part of the anxious advocates of such a step was in not immediately raising the money. They failed to do so, and, a year after, the Faculty passed a vote against receiving women at all, which admits of no misinterpretation. This vote still stands.

At last it is permitted to think that this question is near a tolerably final and, to the majority of the medical world, very satisfactory termination.

The admission of women to the Massachusetts Medical Society, we hope, will shortly be similarly negatived, if again brought up, and some repose may be granted to those who do not live by agitation, and do not believe that either men or women have developed capabilities in our day, which many centuries have failed to reveal.

The other question which this discussion has brought into prominence is one of University government, and has been already touched upon, though as it is by no means a trivial one we venture to refer to it again. The course of this discussion has made it evident that the various schools of a large University cannot safely be governed by any one individual, however able or however earnest, and that there should be, at times, a direct interchange of sentiments between the various faculties and the governing body ordinarily originating legislation.

We have had neither space nor inclination to enter upon the already too vexed question of the general capabilities of women; enough has been said about it. We think, as we have always thought, that time may be safely trusted to dispose of the "woman-movement" to the best advantage of both sexes.

But regarding the extravagances of this movement, as we do, as a temporary enthusiasm, we welcome any indications that old and cherished institutions like the Massachusetts Medical Society and Harvard University, though the future course of one by no means involves that of the other, are not to fall victims in their well-established usefulness to a social fermentation which history will sooner or later refer to simply as a singular phase in the sociology of the latter part of the nineteenth century.

#### RESIGNATION OF THE POST-GRADUATE FACULTY OF THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK; POST-GRADUATE COURSES IN MEDICINE.

EIGHT of the nine gentlemen composing what has been known as the post-graduate faculty of the Medical Department of the University of the city of New York have recently resigned their positions in that college. Their names and professorships are as follows: Dr. D. B. St. John Roosa, Professor of Ophthalmology; Dr. William A. Hammond, Professor of Diseases of the Mind and Nervous System; Dr. Stephen Smith, Professor of Orthopedic Surgery; Dr. J. W. S. Goutley, Professor of Diseases of the Genito-Uri-

nary System; Dr. Montrose A. Pallen, Professor of Gynaecology; Dr. H. G. Piffard, Professor of Dermatology; Dr. James L. Little, Clinical Professor of Surgery, and Dr. F. R. Sturgis, Clinical Professor of Venereal Diseases. Dr. A. E. Macdonald, Professor of Medical Jurisprudence, will still retain his connection with the University. The reason assigned for this action on the part of the members of the post-graduate faculty is, that certain privileges which they claim had been promised them by the regular faculty in connection with the direction of the work of the college have never been fulfilled; so that they have had no voice whatever in its government, and that instead of constituting a faculty in reality, as they were in name, they were merely a set of medical tutors. The members of the regular faculty, on the other hand, deny that such assurances were ever made on their part; but the great stress which the authorities of the college have always laid in their published announcements upon the superior advantages to be derived from the post-graduate course and upon the prominence of the post-graduate faculty, which they claimed as a special feature of the institution, would seem to afford some ground for believing that it was not altogether without cause that the members of the latter consider themselves to have been unfairly treated. It is true that in both the other large medical schools of New York the professors and lecturers in special departments have always held the same relative position to the regular faculty as they; but there is this difference, that in the other colleges these gentlemen have never been organized as a special faculty, and consequently have not been led to consider themselves entitled to the privileges which are supposed to belong to a faculty, if the title is anything more than an empty name. It will probably be some time before the faculties of the various medical schools will become of Dr. Roosa's opinion, that the humblest instructor in any department of the institution should be duly represented in the administration of its government, as is said to be the case in Yale College, for instance.

The upshot of this secession from the University will probably be the abolition of the so-called post-graduate faculty in that institution, and the incorporation of all the special courses in the curriculum proper. Whether this will be to the advantage of the school or not remains to be seen, — as the gentlemen who have resigned are, as a rule, of very high attainments in their special departments.

Another result that seems likely to follow is the organization of a new college expressly devoted to post-graduate instruction in the various special branches of medicine and surgery. It is the opinion of the most enlightened part of the profession in New York that there is an excellent field for such an institution in that city, and, though it would scarcely be self-supporting for a considerable time, and some sacrifices would be necessary at first on the part of those engaged in its work, that there could be little doubt of its ultimate success. There is, indeed, no reason why the same facilities for post-graduate study should not be offered here in America as are offered in the great medical

centres of Europe; and if such schools should be organized on a proper basis, and their various chairs filled by men of the highest ability and eminence, it is altogether likely that a considerable portion of those who now go abroad for the pursuit of special studies would remain at home for this purpose.

#### CHARLES ROBERT DARWIN.

THE death of Charles Robert Darwin on April 20th, at his home in Kent, is a sorrow to all who knew him, and a regret to all lovers of truth and knowledge. To pay our tribute of respect is a sad duty after so irreparable a loss.

The third quarter of our century has been a period of change. The ways of life and the habits of mind that are ours to-day are unlike the living and thinking of thirty years ago. So complete a revolution could be accomplished only by the contributions of many persons of genius and talent. Of the material changes, a theme often used and abused, we have not now to speak, but to the new mental attitude of our generation those must allude who address the public concerning Mr. Darwin's work, because England's most illustrious naturalist has done more than any other intellectual leader to alter our methods of thought.

The young scientist, who, at the age of twenty-two, offered in 1831 his unsalaried service, in order to join the famous voyage of the *Beagle*, probably little realized the controlling influence that that five years' journey around the world would exert over his entire life. It benefited his mind, while it impaired and weakened his body, for he suffered very greatly from seasickness, and remained in consequence a miserable victim of severe digestive disturbances throughout life. It was therefore most fortunate that his private means rendered him independent, for his invalidism would have been fatal to a discharge of regular and confining duties. It was on the voyage of the *Beagle* that his mind became fixed upon the difficult problem of the origin of species, and his memory stored with many facts that later ranged themselves in support of the theory of natural selection.

During the voyage, and after his return to England, he occupied himself with original investigations, which contributed not only to the advancement of science but also to the development of his own mental powers and the strengthening of those faculties, which, later, enabled him to perfect the great achievement of his life. His early writings display his characteristic qualities, — perspicacity and a calm judicial sense. His mind was essentially historical, and sought always to ascertain the succession of events and the causes thereof. He possessed singular acuteness in appreciating the accumulation of effects from causes in themselves slight. This uncommon gift is especially conspicuous in his last published volume upon the earthworm and the formation of vegetable mould, as well as in one of his earliest works, that on coral reefs.

Darwin was a naturalist of what we should now

call the old school. A geologist, botanist, and zoölogist, he looked upon our earth and its living inhabitants as making the immediate nature around us, and he observed and studied rocks, plants, and animals as nature exhibited them for inspection, and took less part in the present prevailing forms of research than younger men trained in the practice of laboratory work. His voyage enabled him to make many important studies on the natural history of little visited countries, and to form extensive collections, which were afterwards worked up by himself and others. The results of these very prolonged labors are recorded in one of the most delightful books of scientific travel we know, *A Naturalist's Voyage Around the World*.

Darwin's earlier scientific writings gave him a high reputation among *savants*; his book on the origin of species, published in 1859, rendered him world renowned, and awakened the most acrimonious, lasting, and wide-spread discussion of modern times. While others stormed and declaimed, some *pro*, some *contra*, the author of the theory of natural selection himself always discussed the matter calmly, and did much more than any one else to call attention to the serious difficulties in the way of the definite demonstration of the theory. Many of us can remember the denunciations of Darwinism once rife, and can hardly fail to contrast the bitter attacks of a few years ago with the universal respect and appreciation now paid to the former victim of reproach and obloquy. The thought that Darwin lived to see his chief work almost universally accepted calls up a pleasant feeling, for, too often, deserved recognition has been bestowed only by posterity.

Since 1859 Darwin has published a series of volumes, containing the results of his later labors, for the most part in further elaboration of the theory of natural selection. The most important of these is the *Animals and Plants under Domestication*; the most interesting, *The Descent of Man*. Perusal of the former is indispensable for the full comprehension of Darwin's theory, and as there are few persons familiar with it, so there are few who thoroughly understand natural selection. All his writings are pregnant with novel views, and highly original. He has been the first to open several new lines of research. He is always careful and accurate, always painstaking, even as to the form of presentation and the style of language. Indeed, all he wrote, even his occasional brief letters to *Nature*, is pleasant and profitable reading.

The Darwinian theory is thoroughly incorporated in our mental life. As a scientific conclusion it is incontrovertibly established. Its greatest effect has been to infuse biology with new interest, and to impart to it problems and possibilities which have captivated a large proportion of the best scientific intellects of our time. Its widest effect has been to convince us that all the organic world is kin, and that man is a modified and bettered development of a lower type. The far-reaching train of consequences from this conviction extends into every department of human belief.

Mr. Darwin was born February 12, 1809, at Shrewsbury. He counts among both his ancestors (Darwins and Wedgewoods) and children persons of

marked superiority of character. His loss will be deeply felt and long mourned, for he was no less charming in private life than prominent in science.

## MEDICAL NOTES.

### PHILADELPHIA.

— At the quarterly business meeting in April of the Philadelphia County Medical Society, the question of the admission of women as members again came up for decision, but this time in a more material form. A few months ago it was decided, at a very large meeting, that women were eligible to membership under precisely the same regulations as men; at this meeting a practical test was made by placing among the candidates to be balloted for the names of five ladies now practicing in the city, and guaranteed as regular by a professor of the Women's Medical College, and by the Board of Censors of the Society. In presenting these names the Board of Censors declared that it had limited itself strictly to the investigation of the professional standing of the candidates in which it had found nothing objectionable. The Board, however, declared that females are ineligible under the By-Laws of the Society, and offered an amendment inserting the words "or she" in the appropriate sections after the word "he" wherever it occurs. This amendment was not agreed to, the Society apparently adhering to the opinion, expressed in the resolution already referred to, that no amendment is necessary. The question excited sufficient attention to bring out a full attendance at the meeting, but the members proved ungallant enough to black-ball every one of the fair candidates. The advocates of equal rights, though defeated, are but little dismayed by this result, which was not unexpected; the mere fact that the names of women candidates have been allowed by the Board of Censors to be presented for balloting is evidence of marked change, as contrasted with the time when men were professionally ostracised for teaching in the Women's College, or for simply consulting with female practitioners. Now there is apparent among some of our principal practitioners much warm rivalry as to who will bid highest for the consulting practice with the weaker vessels, just as in a neighboring community attention has been called recently to a similar break-neck race for the homœopathic and irregular constituency. Such men do exist in the profession even in Philadelphia, but they have not yet succeeded in capturing our medical societies.

— The College of Physicians, at its April meeting, approved of the necessary alterations for the Nurse Registry, which is expected to be in working order by the first of May. At the same meeting Dr. Geo. C. Harlan reported two cases of congenital iridderemia; and Dr. John M. Keating exhibited specimens of malarial enlarged spleen and liver from a child aged twenty months, and specimens of aortic stenosis and extensive atheromatous disease of the aorta from a woman aged one hundred and three years, both obtained from the wards of the Philadelphia Hospital.

## Miscellany.

## LETTER FROM BALTIMORE.

JOHNS HOPKINS UNIVERSITY AND HOSPITAL. THE  
NEW FREE LIBRARY. THE PEABODY INSTITUTE  
LIBRARY. MEDICAL SCHOOLS.

MR. EDITOR.—Not long ago I took advantage of a leisure afternoon, and made my way over to the Johns Hopkins Hospital, thus endeavoring to combine a little relaxation with the acquisition of some knowledge of a not altogether unprofessional kind. So many years have now elapsed since the trustees invited certain gentlemen to send in plans for the hospital, and the subsequent announcement that the work had been begun, that many persons outside of Baltimore think the hospital is now, of course, open, and doing its beneficent work. In spite of all that has been published about this great undertaking, I have reason to know that many otherwise well informed members of the profession have never understood either the magnitude of the work or the conditions and ideas under which the trustees prosecute it. In the first place, Mr. Hopkins selected for his trustees twelve of the very best and ablest gentlemen in the city, gentlemen who took their ground firmly at the outset that no cost in time and trouble to themselves should hurry them into mistakes which they and their successors might have ample leisure to repent. In young and rapidly developing countries men are naturally anxious to see the immediate results of their labors, the consequences of which anxiety are too often narrowness of conception and lack of thoroughness in execution. In their determination to avoid these errors as far as possible the trustees were aided by a wise provision of Mr. Hopkins, that the hospital should be constructed from the income of his bequest, — \$3,500,000, — thus leaving the principal intact, and insuring a sufficient revenue for the proper maintenance of the charity when in operation. The site for the hospital, selected and secured by Mr. Hopkins before his death, comprises upwards of fourteen acres in a desirable though not fashionable part of the city, and is more than a hundred feet above tide water. The view from parts of the land, and especially from the top of the administration building, is very extended. The subsoil is stiff clay covered by a variable thickness of light, sandy loam.

It is now some five or six years since construction was begun, and I am informed that at least six years more will elapse before the hospital is ready for patients. The whole number of separate wards and buildings contemplated by the plan is over a score, and more than half of these are roofed in. Among these are the immense administration building, the nurses' building, and the two pay wards, one for men, the other for women, with ample accommodation for forty patients each. The construction strikes one as simply magnificent; everything is evidently done in the most thorough manner, and the beauty of the buildings is rather that which belongs to thoroughly honest work; all cheap ornamentation is carefully avoided. This is not the place in which to enter into a detailed description of its careful provisions for ventilation and heating, problems so difficult of solution in our climate with its rapid alternations of temperature, with a winter almost arctic, and a summer almost tropical. It has been my fortune to see all the finest hospitals of Eu-

rope as well as of the Eastern United States, and I have no question that the Johns Hopkins will prove to be by far the most perfect in the civilized world. The buildings are of brick, — of which about *fifteen millions* have already been laid, — with trimmings of a very beautiful, fine-grained, bluish stone, which comes, I understand, from Virginia. The front of the administration building contains some large bits of terra cotta made in your South Boston factory. This is not the only contribution which the "Hub" makes us, for all the plans are sent from the office of Messrs. Cabot and Chandler, one of whom comes on occasionally, though the main supervision of the work is in the hands of Dr. John S. Billings. It is the intention to plaster directly on the brick without furring, and the brick walls are allowed to stand such an unusual length of time that no danger from dampness is anticipated. The visitor can inspect many samples of plastering, all the rival holders of patents and processes being invited to put up a few square yards, that each may be proved, and the best finally selected. The various buildings are to be connected by corridors above and a tunnel below. The tunnel will carry the various pipes and wires of the establishment, — the heating is to be derived from both hot water and steam, — and a railway for transporting the food from the kitchen, linen from the laundry, etc., each ward having its own elevator connected with the tunnel. The hospital will have its own greenhouse in a portion of the grounds, all of which will doubtless be kept in the most beautiful order. A piece of land immediately adjoining that devoted to the hospital has been secured for the medical school, work on which has not yet been begun.

Let me urge it upon any of your readers who pass through Baltimore, or happen to be in its neighborhood, to take half a day for the Johns Hopkins Hospital. Those in charge are most obliging, and take pleasure in showing visitors about, especially medical visitors who know what they are looking at.

To turn next to a subject which is not purely medical, but which has an important bearing on education, medical as well as general. I refer to the establishment of libraries. Within a few months Mr. Enoch Pratt, a Northern man, who came many years ago to Baltimore, and has made a large fortune, offered to the city a library building and about eight hundred thousand dollars in cash, provided that the city government will bind itself perpetually to expend fifty thousand dollars per annum in furnishing and maintaining a free public library. This princely offer has been accepted, and the building is in process of construction. Baltimore has at present no large free *circulating* library, though it has a scholars' library which is without a rival in this country, and probably second to none in the world in the special line of work which it undertakes. This is the library of the Peabody Institute, the fine, new hall for the reception of which has only newly been completed. The library is only for consultation, it not being permitted that books should be taken out. No works of fiction or ephemeral literature of any kind are bought; but no pains or expense are spared to secure all books of science, history, biography, etc., of real value. The library is thus in fact a large one, though it only numbers about ninety thousand volumes. As the name indicates, the funds for its establishment and support were given by the late George Peabody, of London, whose home was at one time in Baltimore.

It will readily be seen how immensely valuable is such a library to the Johns Hopkins University. Every facility is offered to instructors and students alike, and the University is spared the expense of accumulating and maintaining a large library of its own. It has, of course, a carefully chosen collection of works of reference, and also a large number of the important current periodicals within its own doors, and always within the easy reach of the members of the University. A number of other books relating to the work going on are also bought, but any of these which are not considered sufficiently important to keep permanently are sold at a reduction from the cost price at the end of one or two years. A book is kept in the library of the University in which those desirous of buying a book thus to be sold can enter an application for it beforehand.

After the completion of the hospital and medical school our city will thus be thoroughly equipped as a centre of education, and of education, moreover, especially of the higher sort. It is probable that the policy of the medical school will be the same as that of the other departments of the Johns Hopkins University, the attainment, namely, of a high grade of work rather than the attraction of a large number of students. We now have three schools of medicine; one giving a degree after two years of study; the others—for the formation of both of which we have to thank (?) Dr. Edward Warren, late of Egypt, now of Paris—giving degrees after one year's study. We are now also threatened with a female medical college. It will be an interesting matter to watch the effect of the opening of the Johns Hopkins Medical School on these institutions. As in nature, so in medical schools; where competition is close and active the fittest survive, and the weak go to the wall. Very truly yours,

PATAPSCO.

BALTIMORE, April 19, 1882.

#### DR. KEITH AND LISTERISM.

MR. EDITOR,—I have received a communication from my friend Dr. Keith, of Edinburgh, in which he complains, and I think it must be admitted not without cause, of the statements made by your correspondent in the *JOURNAL* of January 12th, as to his position with respect to "Listerism."

After denouncing those statements as being wholly incorrect, and moreover unnecessarily so, in view of the fact that your correspondent could readily have ascertained the truth from himself personally, he (Mr. Keith) goes on to say, "It is untrue that I ever once used carbolic spray one tenth stronger than Mr. Lister's five per cent. solution. It is equally untrue that I ever 'denounced Listerism' or 'pronounced against' the use of antiseptic precautions. I said that for some time I had given up the carbolic spray in abdominal surgery as being unnecessary and sometimes dangerous."

"Giving up the carbolic spray in one special operation,—an operation sometimes lasting a couple of hours,—is a very different thing from giving it up in other surgical work, or from giving up the antiseptic principle. I do not now use the spray in ovariectomy, and since I gave it up my results have been better than they latterly were without it, fifty cases giving a mortality of only one."

In your issue of March 2d you express your desire to do justice in this matter, and I think the above cor-

rection is due to Mr. Keith, who feels indignant at the misrepresentation, and is also due to the profession, who ought to know the exact position as to "Listerism" of one who certainly is second to no man living as an ovariotomist. Whether your correspondent should give up the name of the "English ovariotomist" who made to him such untrue statements touches a question of professional ethics which it is unnecessary to discuss here, though my own opinion is very decidedly thereupon.

Yours respectfully, G. H. LYMAN.

121 BOYLSTON STREET, April 22d.

#### ICE-WATER AND DYSPEPSIA.

MR. EDITOR,—If war is to be waged against the use of ice-water as a thirst quencher, at least let such attacks be discriminating.

When correspondents discuss "excessive" employment of it, in "manufactories," or elsewhere, we are ready to "confess judgment" at once.

But the question offers: is ice-water as likely to be excessively used as that which is not iced?

Our impression is that, under some circumstances at least, it is not. And (although perhaps inaccurate) the impression is drawn from a certain amount of actual experience.

Having, for a term of years, been largely interested in extensive wheat harvests in a Southern State, we reached a conclusion, shared by many others of our section, that the use of ice-water, freely dispensed to the harvesters, lessened the frequency of cholera morbus and other such ills, in great part by diminishing the quantity of fluid ingested.

As a matter of course exposure to excessive solar heat was a potent factor in the production of the maladies sought to be averted, and the ice may have had a salutary effect in counteracting this to some degree. However, admitting possible inaccuracy of observation and conclusion, we submit this for what it is worth.

GEO. BYRD HARRISON, M. D.

WASHINGTON, D. C., April 18, 1882.

#### ILLINOIS STATE EXAMINATION FOR CERTIFICATES OF MEDICAL PRACTICE.

THE following are the questions used at the last annual examination of candidates for certificates of practice by the Illinois State Board of Health (Chicago, April 13-15, 1882). To these questions eighty per cent. of correct answers were required.

The numerous inquiries, both from within and without the State, as to the scope and character of these examinations indicate that the publication of the questions may be timely and useful.

It should be noted that, after the session of 1882-83, candidates will be also required to undergo an examination in the branches of a good English education, including mathematics, English composition, and elementary physics or natural philosophy.

Examination in anatomy, by W. A. Haskell, M. D. 1. Name the bones of the carpus. 2. With what bones does the splenoid articulate? 3. Describe a vertebra. 4. Describe the ligaments of the hip-joint. 5. Name and describe the pronator muscles of the forearm. 6. Give the relations of the femoral artery and vein. 7. Describe the thoracic duct. 8. Give the distribution of the median nerve. 9. Where is Wharton's duct? 10. Describe the liver.

Examination in physiology, by John McLean, M. D. 1. What is the action of saliva in digestion, and what are its chemical constituents? 2. Describe the digestion of starch and of fats

3. Give the source and use of animal heat. 4. How is gastric juice formed, and what is its composition? 5. Explain the secretion of bile, its composition and use. 6. Explain the physiology of sleep. 7. Describe the fetal circulation. 8. What nerves are directly concerned in the act of respiration? 9. Describe the circulation of blood in the fetal heart. 10. What causes the sounds of the heart?

Examination in chemistry, by A. L. Clark, M. D. 1. What is meant by a qualitative, and what by a quantitative analysis? 2. How would you test water for organic impurities? 3. Is hard or soft water most liable to contamination by passage through or standing in lead pipes, and why? 4. How would you test a suspected water for salts of lead in solution? 5. Give the names and symbols for ten elementary substances. 6. Name substances with which it is incompatible to unite KI in prescriptions. 7. What chemical elements are contained in pure grade sugar not found in cane sugar? 8. What liquid is the most universal solvent? 9. What is the difference between analysis and synthesis? 10. What precautions are necessary in handling chlorine in the presence of flame or fire?

Examination in general pathology, by R. Ludlam, M. D. 1. Give a definition of disease. 2. What is the difference between a predisposing and an exciting cause of disease? 3. Name the means employed in physical diagnosis. 4. What is meant by a "qualified prognosis"? 5. What forms of inflammation are reparative? 6. How would you recognize the cancerous cachexia? 7. What diseases are incident to the hæmorrhagic diathesis? 8. In what diseases do we often find albumen in the urine? 9. What form of erysipelas is inoculable? 10. Why do attacks of pelvic and portal congestion frequently alternate with each other?

Examination in the practice of medicine, by John McLean, M. D. 1. What are the symptoms of variola, and its treatment? 2. How would you diagnose variola from varicella? 3. Give ætiology, pathology, and treatment of cholera infantum. 4. What is hysteria, and its treatment? 5. Give ætiology, pathology, and treatment of epilepsy. 6. Give diagnosis and treatment of eczema squamosum. 7. Give pathology, causes, and treatment of typho-malarial fever. 8. Give differential diagnosis of diphtheria, and its treatment. 9. Give symptoms and treatment of leucocythæmia. 10. Give symptoms and treatment of acute idiopathic erysipelas.

Examination in surgery, by W. A. Haskell, M. D. 1. Define inflammation. 2. What is the difference between ulceration and mortification? between caries and necrosis? 3. What is a tumor? 4. Give illustrations of a benign, and of a malignant, tumor. 5. Give the treatment of mammary abscess. 6. Explain the *modus operandi* of reduction of the iliac dislocation of the head of the femur by manipulation. 7. Give the differential diagnosis of compression and concussion of the brain. 8. Give the differential diagnosis of inguinal hernia and hydrocoele of the cord. 9. Give the diagnosis of morbus coxarius: (a) During the first stage before the occurrence of effusion. (b) During the stage of effusion, the capsule of the joint remaining entire. 10. Give the general treatment of fractures of the lower extremities.

Examination in obstetrics, by A. L. Clark, M. D. 1. Define obstetrics. 2. How can you differentiate pregnancy from ovarian tumor or cyst? 3. At what period or stage of labor is there the greatest danger to the mother, and what is the danger? 4. Give the contra-indications to the use of ergot. 5. Under what circumstances should version be performed? 6. Will the mother's blood pass out from the umbilical cord unless this be tied before being cut? 7. Give diagnosis and treatment of puerperal eclampsia. 8. Give diagnosis and treatment of hydrocephalus of the infant during parturition. 9. What is the shape of the posterior fontanelle? 10. Give the treatment for prolapse of the funis umbilicalis.

Examination in gynecology, by R. Ludlam, M. D. 1. What are the uses of the uterine sound? 2. What diseases are accompanied by an increased depth of the womb? 3. In constipation, with or without hæmorrhoids, which ovary is most frequently inflamed, and why? 4. What intra-pelvic inflammation is most frequently rheumatic? 5. What diseases are followed by fixity, or anchorage of the uterus? 6. Name the most frequent cause of menorrhagia in women who have had one or more children. 7. Define a menstrual headache, and give the treatment for it. 8. What are the sources of puerperal traumatism, and what are the most serious lesions that may result from it? 9. In a lying-in patient, how would you distinguish a physiological from a pathological chill? 10. When are mammary abscesses salutary?

Examination in materia medica and therapeutics, by J. H. Rauch, M. D. 1. Classify remedial agents, broadly, by their actions and uses. 2. Name some of the principal agents in each class. 3. Name the principal nino genital remedies, and write

five prescriptions, embracing a different one in each. Give the indications intended to be met by each prescription. 4. What alteratives, emetics, and cathartics are indigenous in Illinois? 5. Give the sources, active principles, two or more official preparations, and uses of (a) camphor, (b) ergot, (c) nux vomica, (d) opium, (e) physostigma. 6. Describe the therapeutic uses of the bromides, and write prescriptions for each of three of them, with indications. 7. Mention some of the most important recent additions to the materia medica, with their uses. 8. Give the therapeutic uses and applications of *aqua fluviatilis* or *fontana*. 9. Mention the different official preparations of antimony. 10. Give the doses of (a) ammonii phosphas, (b) odoformum, (c) strychni sulphas, (d) acidum boracicum, (e) ext. belladonnæ alc., (f) atropiæ sulphas, (g) resina podophylli, (h) tr. aconiti rad., (i) extr. gelsemii fld., (k) acidum hydrocyanicum dilutum.

Examination in hygiene, by J. H. Rauch, M. D. 1. Give the prophylaxis of small-pox, and the measures to prevent its spread on the appearance of the first case. 2. To what extent should vaccination be made compulsory in the United States, and why? 3. What is "ground-water," and what is its agency on health? 4. Describe the principal disinfectants, their applications and modes of use. 5. Formulate a set of rules for school hygiene. 6. What is "sewer-gas," and what evils are ascribed to it? 7. Give the differential diagnosis, for sanitary purposes, of (a) scarlatina, (b) rubella, (c) varicella, (d) variola, (e) febris flava, (f) cholera Asiatica, (g) trichiniasis. 8. Describe vaccination and its progress through the different stages, the effects ascribed to it, its complications, and the ages at, or conditions under, which it should be repeated. 9. What are the chief causes of an excessive mortality, and their remedies? 10. Describe Pasteur's recent experiments.

Examination in medical jurisprudence, by J. H. Rauch, M. D. 1. At what age is the fœtus viable, and what are the signs and indications of such age? 2. What precautions—other than for the safety of the subject—would you observe in the exhibition of an anæsthetic, and why? 3. How would you determine whether lesions, injuries, or discolorations, found on a cadaver, were produced before or after death? 4. What is the course of procedure in the commitment of persons to an insane asylum in this State? 5. Has the registration of vital statistics any legal bearing, and, if so, what?

#### AMERICAN MEDICAL ASSOCIATION.

The thirty-third annual session will be held in St. Paul, Minn., on Tuesday, Wednesday, Thursday, and Friday, June 6, 7, 8, 9, 1882, commencing on Tuesday at eleven A. M.

The delegates shall receive their appointment from permanently organized State Medical Societies, and such County and District Medical Societies as are recognized by representation in their respective State Societies, and from the Medical Department of the Army and Navy, and the Marine Hospital Service of the United States.

Each State, County, and District Medical Society entitled to representation shall have the privilege of sending to the Association one delegate for every ten of its regular resident members, and one for every additional fraction of more than half that number: *Provided*, however, that the number of delegates for any particular State, territory, county, city, or town shall not exceed the ratio of one in ten of the resident physicians who may have signed the Code of Ethics of the Association.

Secretaries of Medical Societies as above designated are earnestly requested to forward, at once, lists of their delegates.

Sections. Practice of Medicine, Materia Medica, and Physiology: Dr. J. A. Oesterlony, Louisville, Ky., Chairman; Dr. D. J. Roberts, Nashville, Tenn., Secretary. Obstetrics and Diseases of Women and Children: Dr. H. O. May, Boston, Mass., Chairman; Dr. C. V. Mottram, Lawrence, Kan., Secretary. Surgery and Anatomy, Dr. ———, Chairman; Dr. W. A. Byrd, Quincy, Ill., Secretary. State Medicine: Dr. A. L. Gibon, U. S. Navy, Chairman; Dr. J. H. Sears, Waco, Texas, Secretary. Ophthalmology, Otolaryngology, and Laryngology: Dr. ———, Chairman; Dr. J. Solis Cohen, Philadelphia, Secretary. Diseases of Children: Dr. S. C. Bussey, Washington, D. C., Chairman; Dr. William Lee, Baltimore, Md., Secretary. Dentistry: Dr. D. H. Goodwillie, New York city, Chairman; Dr. T. W. Brophy, Illinois, Secretary.

A member desiring to read a paper before any Section should forward the paper, or its title and length (not to exceed twenty minutes in reading), to the Chairman of the Committee of Arrangements at least one month before the meeting. — *By-Laws*.

Committee of Arrangements: Dr. A. J. Stone, St. Paul, Minn., Chairman.

WILLIAM B. ABRINSON, M. D., *Permanent Secretary*.  
PHILADELPHIA, 1400 PINE STREET.

## REPORTED MORTALITY FOR THE WEEK ENDING APRIL 15, 1882.

| Cities.                           | Population by Census of 1880. | Reported Deaths in each. | Deaths under Five Years. | Percentage of Deaths from         |                |                       |                |            |

Deaths reported 2907 (no reports from St. Louis, New Orleans, and Cleveland); 1125 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 673, lung diseases 449, consumption 394, diphtheria and croup 167, scarlet fever 129, small-pox 82, measles 64, typhoid fever 51, diarrheal diseases 50, whooping-cough 34, cerebro-spinal meningitis 31, erysipelas 26, malarial fevers 22, puerperal fever 14, typhus fever three. From *measles*, New York 33, Chicago seven, Philadelphia and Pittsburgh six each, Brooklyn five, Cincinnati four, Buffalo two, Baltimore one. From *typhoid fever*, Philadelphia 25, Cincinnati four, New York, Chicago, and Baltimore three each, Boston, District of Columbia, Buffalo, and Charleston two each, Brooklyn, Pittsburgh, Milwaukee, Holyoke, and Waltham one each. From *diarrheal diseases*, New York 16, Chicago nine, Boston six, District of Columbia five, Baltimore four, Pittsburgh three, Brooklyn and Buffalo two each, Cincinnati, Milwaukee, and Charleston one each. From *whooping-cough*, New York 18, Brooklyn five, Philadelphia and Baltimore two each, Chicago, Boston, Pittsburgh, Buffalo, Providence, Charleston, and Cambridge one each. From *cerebro-spinal meningitis*, Buffalo nine, New York eight, Pittsburgh four, Philadelphia and Chicago two each, District of Columbia, Milwaukee, Worcester, New Bedford, Haverhill, and Milford one each. From *erysipelas*, New York nine, Boston four, Philadelphia, Brooklyn, Cincinnati, and Pittsburgh two each, Chicago, Baltimore, Buffalo, Newburyport, and Weymouth one each. From *malarial fevers*, New York 13, District of Columbia four, Brooklyn two, Baltimore, New Haven, and Nashville one each. From *puerperal fever*, New York, Chicago, Boston, and Cincinnati two each, Philadelphia, Pittsburgh, Milwaukee, New Haven, Holyoke, and Newburyport one each. From *typhus fever*, New York two, and Charleston one.

One hundred and seventeen cases of small-pox were reported in Cincinnati, Pittsburgh 19, Brooklyn eight, Baltimore six, Buffalo four, District of Columbia and Milwaukee each two; diphtheria 10 cases, scarlet fever 12, and typhoid fever five, in

Boston; scarlet fever 16 cases, and diphtheria two, in Milwaukee.

In 38 cities and towns of Massachusetts, with a population of 1,039,313 (population of the State 1,783,086), the total death-rate for the week was 22.26 against 22.83 and 21.80 for the previous two weeks.

For the week ending March 25th, in 173 German cities and towns, with an estimated population of 8,418,545, the death-rate was 27.1. Deaths reported 4388; under five 2063; pulmonary consumption 731, acute diseases of the respiratory organs 492, diphtheria and croup 232, diarrheal diseases 140, scarlet fever 79, whooping-cough 75, typhoid fever 54, measles and röteln 39, puerperal fever 21, small-pox (Königsberg, Munich, Essen four, Bochum, Koblenz, Strassburg, Darmstadt) 10, typhus fever (Königsberg, Stargard, Tilsit two, Posen) five. The death-rates ranged from 15.7 in Halle a. S. to 38 in Strassburg; Königsberg 27.7; Breslau 34.5; Munich 35.3; Dresden 23.8; Berlin 22.6; Leipzig 24.3; Hamburg 27.2; Hanover 23.8; Bremen 28; Cologne 26.2; Frankfurt a. M. 24.5.

In the 28 English towns, with an estimated population of 8,457,514, for the week ending April 1st, the death-rate was 23.2. Deaths reported 3767; acute diseases of the respiratory organs (London) 408, whooping-cough 226, measles 181, scarlet fever 71, fever 61, diarrheæ 43, diphtheria, 42, small-pox (London) 9. The death-rates ranged from 10.6 in Huddersfield to 34.3 in Oldham; Leeds 21; London 22.7; Sheffield 22.6; Bristol 24.1; Liverpool 26.9; Manchester 32.7; Birmingham 20.8.

For the week ending April 1st in the Swiss towns, population 479,934, there were 64 deaths from acute diseases of the respiratory organs, pulmonary consumption 43, diarrheal diseases 28, diphtheria and croup 17, whooping-cough and typhoid fever each four, puerperal and scarlet fever each two. The death-rates were, Geneva 29.3; Zurich 41.6; Basle 19.6; Berne 40.2.

The meteorological record for the week ending April 15th, in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the U. S. Signal Corps:—

| Date.               | Baromet-<br>er. | Thermom-<br>eter. |          |          |            | Relative<br>Humidity. |             |       | Direction of<br>Wind. |            |             | Velocity of<br>Wind. |            |             | State of<br>Weather. <sup>1</sup> |            |             | Rainfall.                |                      |

#### DR. HERBERT SHURTLEFF.

At the meeting of the Plymouth District Medical Society, held in North Abington, Wednesday, the following resolutions on the death of Dr. Shurtleff were passed:—

If *thereas*, We are called suddenly and unexpectedly to mourn the loss of our highly esteemed associate, Dr. Herbert Shurtleff, whose intently death was the sad result of faithful and untiring devotion to his professional duties:—

*Resolved*, That we deeply sympathize with the family thus suddenly bereaved of a beloved husband and father, and with the people where he resided, who had unbounded confidence in his skill and faithfulness as a physician, as well as a high appreciation of his social and moral qualities as a citizen and friend.

*Resolved*, That, as a Society, we shall ever hold in grateful remembrance his genial disposition, his warm and lasting interest in the Society, and his worth and high standing as a member of the profession.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM APRIL 15, 1882, TO APRIL 21, 1882.

CORBUSIER, W. H., captain and assistant surgeon. Now awaiting orders, to report in person to the commanding general, Department of the East, for assignment to duty. S. O. 78, C. S., A. G. O.

DAVIS, W. B., captain and assistant surgeon. Now awaiting orders, to report in person to the commanding general, Department of the Platte, for assignment to duty. S. O. 78, C. S., A. G. O.

KING, WM. H., captain and assistant surgeon. To be relieved from duty in Department of the East on receipt of this order, and then to proceed to his home.

Granted leave of absence until further orders, on account of sickness. S. O. 82, A. G. O., April 10, 1882.

GILLENLAP, CHARLES B., major and surgeon. In accordance with paragraph 12, S. O. 78, C. S., from headquarters of the Army, relieved from duty in this Department. S. O. 57, Department of Dakota, April 11, 1882.

GARDNER, W. H., captain and assistant surgeon. His assignment to duty at Fort McKavett, to relieve Surgeon Waters, revoked, and to report to the commanding officer, Fort Davis, Texas, for duty as post surgeon. S. O. 38, Department of Texas, April 14, 1882.

LAUDERDALE, J. V., captain and assistant surgeon. Paragraph 1, S. O. 47, C. S., from these headquarters, in regard to him, revoked; and he will proceed to Fort Sully, D. T., and report to the commanding officer of that post for duty. S. O. 59, Department of Dakota, April 13, 1882.

BROWN, P. R., captain and assistant surgeon. To be relieved from duty in Department of Texas on receipt of this order; to proceed to New York city, and, on arrival, report by letter to the Surgeon-General. S. O. 88, A. G. O., April 17, 1882.

FISLEY, J. A., captain and assistant surgeon. Relieved from duty at Fort Concho, Texas, and assigned to duty as post surgeon at Fort McKavett, Texas, relieving Surgeon Waters. S. O. 38, C. S., Department of Texas.

KILBOURN, H. S., captain and assistant surgeon, having re-

ported in person at these headquarters, will proceed to Fort Shaw, Mont. T., and report to the commanding officer of that post for duty. S. O. 60, Department of Dakota, April 14, 1882.

CORBUSIER, WILLIAM H., captain and assistant surgeon. Assigned to duty as post surgeon at Fort Mackinac, Mich. S. O. 67, Department of the East, April 15, 1882.

DAVIS, WILLIAM B., captain and assistant surgeon. So much of paragraph 12, S. O. 78, April 5, 1882, from A. G. O., as directs him to report for duty to the commanding general, Department of the Platte, is amended so to direct him to report in person for duty to the commanding general, Department of Dakota. S. O. 87, A. G. O., April 15, 1882.

MASSACHUSETTS COLLEGE OF PHARMACY. — The fourteenth annual commencement of the Massachusetts College of Pharmacy was held in the College Hall, 1151 Washington Street, Boston, on Wednesday evening, April 5, 1882. The degree of Graduate in Pharmacy was conferred upon the following gentlemen of the class of 1882 by the president, Mr. Solomon Carter: Nathaniel Herbert Clark, Richard Barker Dawson, Henry Eugene Fleming, Franklin Willard Freeman, Lyman Whitney Griffin, Edwin Hirth, Edgar Clarence Maxey, Edward Franklin Otis, Daniel Ellis Ray, George Melzar Stetson, James Henry Thompson, Henry Thacher.

SUFFOLK DISTRICT MEDICAL SOCIETY. — The annual meeting of the Suffolk District Medical Society will be held at 19 Boylston Place, on Saturday, April 29th, at 7.45 p. m. The following papers will be presented: Scrofula, or Hodgkin's Disease, Dr. G. Liebmann. Apparatus for Spinal Curvature, Dr. E. H. Bradford. Report of Cataract Operations, Dr. B. Joy Jeffries. Exhibition of Obstetrical Manikin. Election of officers. Supper at the usual hour. Members are requested to notify the secretary of any change of address or failure to receive notices of meetings. H. C. HAVEN, Secretary.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting of the Society will be held on Monday, May 1, 1882, at eight o'clock p. m., at the hall, 19 Boylston Place. Reader, Dr. Abner Post. Dr. M. H. Richardson will show a Dissection of the Nerves of the Hand. C. M. JONES, Secretary.

GYNÆCOLOGICAL SOCIETY OF BOSTON. — The next regular meeting will be held at the Medical Library Rooms, on the first Thursday of May, at eleven o'clock a. m. W. S. BROWN, M. D., will present a paper introducing a discussion upon Septicæmia in Women. Profession invited.

HENRY M. FIELD, M. D., Secretary.

BOOKS AND PAMPHLETS RECEIVED. — The International Scientific Series, Suicide: An Essay on Comparative Moral Statistics. By Henry Morselli, M. D. New York: D. Appleton & Co. 1882.

Myxœdema. By A. Clifford Mezer, M. D., F. R. M. S., Instructor in Histology in the College of Medicine, Syracuse University. A paper read before the Syracuse Medical Association, February 15, 1881. (Reprint from the Medical Record.)

CASES OF PULMONARY CONSUMPTION FOLLOWED BY RECOVERY, OR BY ARREST OF THE DISEASE.<sup>1</sup>

BY FRANCIS MINOT, M. D.,

*Physician to the Massachusetts General Hospital.*

EVERY practitioner of much experience occasionally meets with instances of recovery from pulmonary consumption, or of long-continued arrest of the disease. Dr. Flint, in his valuable work on Phthisis, gives the histories of forty-four recoveries, besides thirty-one cases of arrested or non-progressive phthisis, from which it would appear that neither age, sex, family predisposition, nor hæmoptysis are unfavorable circumstances as elements in the prognosis. The great fatality of the disease should lead us to study such cases in the hope of obtaining some hints which may guide us in the treatment, or at least in the prognosis of this malady. Of the following cases perhaps three can be considered as examples of recovery, one of which was followed, ten years afterwards, by a recurrence of the disease, which proved fatal.

## CASE I. PULMONARY SYMPTOMS FOR SEVERAL MONTHS; SIGNS IN RIGHT APEX; TWO YEARS AFTERWARDS GOOD HEALTH AND ABSENCE OF PHYSICAL SIGNS.

A hack driver, aged thirty, much exposed to weather, often up all night, and when off the box spending most of his time in a small, ill-ventilated room with several other coachmen; had a cough during the whole of the winter of 1859-60, which began in an acute attack of chest affection of some kind. Considerable expectoration, chiefly early in the morning. Never hæmoptysis. Steadily lost flesh and strength from the first. No night sweats.

March 7, 1860, dullness below right clavicle, especially towards outer extremity. Prolonged expiratory murmur throughout whole of same region. Inspiration loud, somewhat harsh, with occasional moist clicking sounds. After cough abundant explosion of moist crackling. Some crackling after cough in right supra-spinous fossa. Heart sounds normal. Pulse 96. Patient is a large, stout man, but appears weak and depressed. Features somewhat pinched. Complains of feeling cold in spite of extra clothing, but declares he is not sick, and only applies for advice at the request of friends. (Cod-liver oil; croton oil to chest.) Two years afterwards, in April, 1862, he consulted me about a pain in the left side, apparently neuralgic, and without physical signs. Examination of the right apex showed roughness of the respiratory sound, with prolonged expiratory murmur, below the clavicle, but no râle, even after cough. There was but little difference in the percussion sound between the two sides of the chest. No cardiac murmur. No record concerning cough. He had kept steadily at work, and his health had "considerably improved."

The absence of proper details leaves us in doubt whether a *considerable improvement* in health can be regarded as a complete recovery from the symptoms of pulmonary disease; but the examination of the chest shows that the local disease had retrograded, and was perhaps in a state of permanent arrest.

CASE II. HÆMOPTYSIS, WITH GENERAL SYMPTOMS OF PHTHISIS, SIGNS IN LEFT APEX; RAPID IMPROVEMENT AND COMPLETE RESTORATION TO HEALTH; TEN YEARS AFTERWARDS RECURRENCE OF THE DISEASE AND DEATH IN SIX MONTHS.

An unmarried lady, thirty-five years old. Her mother died with pulmonary symptoms, over sixty years of age. Health delicate; she was liable to "take cold," and suffered from dysmenorrhœa, rheumatism, and dyspepsia. Short in stature, slender. In January, 1865, a severe catarrh, lasting many weeks, for which she took fusel oil, and had croton oil and blisters applied to the chest. My notes state that some trouble in the apex of the left lung was suspected, but no signs were recorded. She recovered perfectly, and became unusually well, gaining eight pounds in weight. In August, 1866, she took cold, and had a slight cough, with debility. August 31st hæmoptysis twice. This occurred a few days after menstruation.

September 1st, dullness below outer extremity of left clavicle; respiration rough, with clicking; fine bubbling râle after cough in left supra-spinous fossa. (Fusel oil; croton oil to chest; full inspirations to be practiced regularly.) Immediate improvement in general health.

December 17th, some hæmoptysis for several days. She had gained four pounds in weight. (Cod-liver oil.)

January 31, 1867, increase of cough and expectoration, and subjective "rattling" within the chest; nevertheless she rapidly improved, and on March 31st was apparently in perfect health.

October 10th her weight was one hundred and twenty-five pounds, more than ever before in her life. Occasional cough and slight expectoration in the morning. She walks without fatigue. Catamenia regular, digestion good. She had taken regularly half an ounce of cod-liver oil twice daily, except when she had been able to procure plenty of good cream.

November 20th, some dullness below left clavicle to whole extent horizontally, and two or three inches vertically. In same region occasional dry, creaking sounds on full inspiration. No crackling after cough, no râles, bronchial respiration, bronchophony, or other signs anywhere.

August 9, 1869 (four years from first sickness), strength, color, and flesh perfectly good; catamenia regular. No dullness in left apex; some dry sounds below left clavicle and in supra-spinous fossa; no moist râles heard anywhere, even after cough.

This patient afterwards went to Europe, where she was married, and remained during the rest of her life. Her health continued to be good until 1875, when she had a "rheumatic attack," which prostrated her very much. She died, November 1, 1876, of "consumption of the lungs" the symptoms of which began six months previously. I have not been able to obtain any further particulars of the case.

Here, as in the preceding case, the disease remained limited to its original seat, the active processes ceased, and the patient was in the enjoyment of good health, with no pulmonary symptoms for about nine years. Whether the return of the lung disease could be ascribed to any particular cause we have no means of knowing. The patient was remarkably faithful in carrying out the treatment, and to this I ascribe some share of her improvement.

<sup>1</sup> Read before the Boston Society for Medical Improvement, April 24, 1882.

CASE III. FAMILY PREDISPOSITION TO CONSUMPTION; COUGH, HÆMOPTYSIS, GENERAL SYMPTOMS OF PHTHISIS, WITH PHYSICAL SIGNS; RAPID IMPROVEMENT AND APPARENT RECOVERY; SUDDEN DEATH ELEVEN YEARS AFTERWARDS, PRESUMABLY FROM CARDIAC AFFECTION.

A gentleman, twenty-eight years old, single. His mother and one brother died of consumption. Previous health good. In April, 1869, he "caught cold," coughed, and raised a considerable quantity of blood. The only signs found were jerking inspiration in left front, and a remarkably loud arterial whiff below outer extremity of left clavicle. Respiratory murmur everywhere rather faint; no râles. May 6th, increased cough, sweating at night, hoarseness of voice; abundant moist râles in right apex, front and back. (Churchill's hypophosphites, whiskey, cold sponge bathing, iodine to chest.) He improved rapidly, strength and weight good; he seemed well, except for slight morning cough and expectoration. The voice was nearly free from hoarseness, but he was not able to sing, as formerly. October 19th, dullness throughout right upper front, with marked depression of chest wall. Clicking râle on full inspiration. Amphoric respiration in right supra-spinous fossa. Resonance of voice throughout right summit. Subjective "rattling" about the base of the neck, especially at night. He passed the following winter (1869-70) in Europe, continuing the treatment, and returned in good condition. October 10, 1870, the depression of chest wall below right clavicle was very striking; the râles were drier than before; the amphoric respiration in the supra-spinous fossa had disappeared. General health apparently perfectly good. December 9, 1872, he weighed one hundred and fifty-three pounds, and was apparently in perfect health. Below right clavicle for a space of several inches, vertically, corresponding to the sunken chest wall, there was a distant, harsh, cavernous sound with both inspiration and expiration. He had taken no medicine, except from two to eight ounces of whiskey daily. In 1878 he was married. In the spring of 1880 he complained of indefinite symptoms, which he suspected might be caused by disease of the heart, and he appeared hypochondriacal. He did not consult me, and I do not know whether there was any ground for his suspicion, but he died suddenly, while in a railroad train, after complaining for a few minutes of faintness. There was no autopsy.

This case is interesting on account of the apparently complete recovery of a patient with a family predisposition to consumption, whose right lung had been destroyed to such an extent as to cause much depression of the front wall of the chest. The fortunate event may in part be attributed to the perseverance with which the treatment was carried out, and to the means which the patient possessed of traveling, riding on horseback, and living much in the open air.

CASE IV. HÆMOPTYSIS FIVE YEARS AGO; SIGNS OF STRUCTURAL DISEASE OF LUNG CONTINUING EVER SINCE, WITH APPARENT GOOD HEALTH.

A young lady, eighteen years old, well nourished, blonde, previously very healthy. Parents both living and well; no consumption in the family of either. March 21, 1877, during the monthly period, she coughed up bloody mucus. No fever. Abundant crackling and creaking sounds were heard in the right lower front, lateral, and

posterior regions of the chest. In upper front and back, respiration normal. No dullness anywhere. The signs disappeared completely the next day, and she appeared quite well. There was no change in her general condition during the summer, which she spent at the sea-shore and in traveling, taking cod-liver oil regularly.

October 2d. Decided dullness below right clavicle. Moist creaking sounds at the end of inspiration in every part of right front and lateral region and upper half of back, but most marked between mamma and right edge of sternum, where there is also a fremitus perceptible to the finger. The patient refers to a peculiar sensation at this spot. Pulse 72; temperature of axilla 97.9° F. There had been scarcely any expectoration during the summer.

She went abroad for two years, returning in October, 1879. She gained constantly, and never had much cough or expectoration. She took cod-liver and iron, and thought she derived great benefit from the inhalation of the vapor of tar. Weight, in December, 1879, one hundred and fourteen pounds. January 8, 1880, she raised a few drops of blood during the menstrual period, the first for about a year. She was apparently well, though delicate. She lived carefully, but went into society in the evening. She had scarcely any cough, and no expectoration. Catamenia regular and normal. No sweating. Tall in stature and under weight. Pulse 84. Chest wall below right clavicle considerably sunken, and dull on percussion for a breadth of two or three inches. Moist clicking or bubbling râle on full inspiration, with crackling after cough throughout whole of upper two thirds of right front. Râle is also heard beneath axilla and below mamma. Loud resonance of voice in same regions. Behind, the râle is limited to the space between the upper part of scapula and spinal column of right side. On quiet breathing the respiratory murmur in the right upper front is harsh, compared to the left. No cardiac murmurs; second sound of heart not much attenuated. No signs in left chest. She still takes cod-liver oil, and has a vessel of tar by her bedside, the vapor of which fills the room. December 5, 1881. By report she is quite well, and has had no cough during the past six months. She continues in the same condition at the present time.

The pathology of this case is obscure. The hæmoptysis invariably occurred during menstruation, which has always been normal in all respects. Hence we may infer that it resulted from congestion of the pulmonary vessels, as is confirmed by the fact that there was considerable variation in the extent of the signs after it. That some destruction of the lung tissue has taken place seems, however, evident from the persistence of well-marked signs of softening about the right apex, with sinking of the chest wall. The almost complete absence of cough and expectoration is remarkable, but such cases have been observed. I have had one under my care, in which the disease was revealed by the autopsy, and two are reported by Dr. H. A. Lediard in the *London Medical Times and Gazette* for April 1, 1882. Finally, the preservation of good general health during the whole period from the first attack of hæmoptysis to the present time is as unusual as it is gratifying. It may, perhaps, be in part accounted for, as in the two preceding cases, by the fidelity with which the patient carried out the treatment, and the possession of facilities for travel, etc.

CASE V. RATIONAL AND PHYSICAL SIGNS SINCE FEBRUARY, 1880; IN SIX MONTHS IMPROVEMENT WHICH HAS STEADILY CONTINUED. APPARENT GOOD HEALTH AT THE PRESENT TIME.

A young lady, fifteen and a half years old, of rather slender frame, but general good health. No lung disease in family of either parent. In February, 1880, signs of failure of strength, loss of appetite and of cheerfulness, dyspeptic symptoms, etc. In May, cough, especially troublesome early in the morning. It increased in June. Rapid loss of flesh; dusky hue of the surface; cold hands and feet; shortness of breath on exertion; no hæmoptysis. Physical signs first noted June 19th, dullness, with harsh expiratory murmur below left clavicle, and in upper part of left back, between scapula and spinal column; and bronchophony in latter place, also below inner extremity of clavicle. Cough spasmodic, lasting an hour or more, accompanied by frothy expectoration. Sweating at night. Pulse 120. Extract of malt, whiskey, phosphoric acid, tincture of belladonna at night; full inspirations practiced regularly. The patient went to the sea-shore June 25th, and a slight improvement immediately showed itself, which progressed slowly but without interruption. She passed almost the whole day in the open air. The cough became less urgent at night, the appetite improved. She could, however, walk but a short distance; there was much emaciation, shortness of breath, and duskiess of surface.

August 12th. Weight eight-two pounds, being the same as when she left town. Pulse 108; temperature 99.6° F. Principal signs noticed were harsh expiration with resonance of voice, and especially of whisper below inner end of left clavicle, and between upper part of left scapula and the spinal column. Some general improvement shown by increased animation, and interest in people and things about her, and by some gain in strength. She can walk a little, and drives a good deal. Appetite somewhat improved. The nights are better; cough less urgent, softer and looser, and has lost its paroxysmal character. From this time the improvement was regular, and comparatively rapid. The patient returned from the sea-shore early in November in apparent good health, appetite good, complexion blooming; very little cough. She could walk two miles, and spent almost the whole day in the open air. The signs were but little altered, except that the bronchial respiration in the left upper back had disappeared. There was abundant moist crepitation after cough in the left axilla. The treatment had been assiduously carried out. November 26th, she raised a little blood for the first time. A year later she was the picture of health, weight one hundred and twelve and a half pounds, no cough, no expectoration. The only signs were some fine, dry, crumpling sounds below left mamma, at the end of full inspiration. Pulse 90 to 100. Menstruation appeared for the first time January 8, 1882. It lasted four days, was rather scanty, and without pain. March 31st, below left mamma and in the lateral region of the same side are heard a few bubbling râles, somewhat increased after cough. The upper part of the chest is quite free from râle. Pulse 88 to 92. There have been some cough and expectoration of late, owing apparently to a cold. The general condition continues as good as before. Weight one hundred and twelve pounds. The monthly periods have been irregular and scanty.

The duration of this case up to the present time is

two years and two months. The patient cannot be considered well, and certainly is not free from danger of a return of the grave symptoms which once threatened her life. It may be considered as one of "arrested phthisis." There is, however, a reasonable prospect of eventual recovery.

CASE VI. FAMILY PREDISPOSITION; COUGH, EXPECTORATION; SIGNS IN LEFT LUNG; RAPID DEVELOPMENT OF GENERAL SYMPTOMS; GREAT IMPROVEMENT WHILE AT THE SEA-SHORE; APPARENT RECOVERY WITH PERSISTENCE OF THE PHYSICAL SIGNS.

A married lady, thirty-eight years old, has four children, youngest four years old; no miscarriages. Her mother and two of her sisters died of consumption. Health good till the winter of 1879-80, when she had dry cough and loss of flesh. In April, 1880, a little expectoration; never hæmoptysis; chest wall in left front somewhat sunken. Dullness, with clicking, bubbling râle after cough in left upper front and back. During the summer she was at Rye Beach, where at first all the symptoms were greatly increased; she lost much flesh and strength, the voice became husky, and her condition was very discouraging. In a few weeks she began to amend, and the improvement continued during the whole of her stay at the sea-shore. August 15th, she weighed one hundred and seventeen pounds, but before leaving Rye Beach in September, she weighed one hundred and twenty-seven pounds, and on November 27th, one hundred and forty pounds. September 28th, there was dullness in left subclavicular region, with depression of the chest wall; the râle had greatly diminished in the same region, and could not be heard at all behind, though the respiration was louder and harsher there than on the right side. The general condition was correspondingly good; there was very little cough, scarcely any expectoration, appetite and sleep good, catamenia normal, pulse 108, voice still "veiled." In October, 1881, after another season at Rye Beach, during which she was as well as usual, without cough or expectoration, her weight was one hundred and forty-seven pounds. She was then taking two ounces of whiskey three times a day, no medicine. She remains in the same general condition, but there is still some râle in the left upper front.

This case must also come under the head of "arrested phthisis," but we may hope the patient may eventually recover. This case and the last are remarkable instances of rapid and progressive improvement during a residence at the sea-shore, a situation which is not usually considered favorable for patients with chronic lung diseases, especially where the temperature is very low, as at Rye Beach. I visited the last patient during one of the hottest days of the summer of 1879, and found her in a room which was made only comfortably warm by a good fire. The other patient (Case V.) always felt more comfortable during an east wind.

CASE VII. SUDDEN HÆMOPTYSIS DURING APPARENT GOOD HEALTH IN A PATIENT WHOSE HUSBAND WAS IN ADVANCED PHTHISIS; SIGNS AND SYMPTOMS OF PHTHISIS; GRADUAL IMPROVEMENT; GOOD HEALTH AND WEIGHT WITH PERSISTENCE OF SIGNS TEN YEARS AFTERWARDS.

A married lady, thirty years old, in good health. Her husband had been ill with consumption for three

years, and was now in an advanced stage of the disease. In August, 1870, while in Boston, sudden hæmoptysis in night-time. She raised about half a pint. This was one week before the menstrual period. The weather was extremely hot. The catamenia appeared at the regular time, but slightly diminished in quantity. Abundant crackling after cough in right upper front was noted August 27th, and in left upper front October 25th. She had some cough, slight expectoration, and hoarseness. About this time she became pregnant. She went to the South in the winter, where her husband died in February, 1871. She was confined without accident in July following, having been in very fair health previously, with very little cough. She raised a little blood from time to time. In May, 1873, no dullness was found in front, and no râles, but the expiratory murmur was exaggerated below right clavicle; behind, moist crackling after cough between left scapula and spinal column; also in left lateral region and below left mamma. She passed the summer in Bethlehem, N. H., in good health, and gained seventeen pounds. October 22, 1878, weight good; menstruation regular; slight cough and expectoration; hæmoptysis from time to time; decided dullness throughout left front, with moist râles after cough; strength and wind not good. She spent the next three winters in Europe, and another in Norfolk, Va. While there her weight was one hundred and thirty pounds. In June, 1879, the general condition and symptoms were about the same. In October, 1879, "health for the past year quite good, with very little cough, and no hæmoptysis. She looks perfectly well; weight one hundred and thirty-one pounds; voice good; catamenia regular."

This case may be called one of tolerated phthisis. There is no evidence of retrogression of the lesions; on the contrary, they are apparently advancing, but at an extremely slow rate, so that there is a reasonable prospect of eventual recovery, especially as the general condition is so satisfactory. The case is also of interest as one of possible contagion. The patient's child is living, and though somewhat delicate is in good health.

The treatment of these cases did not differ essentially, I believe, from that employed by most physicians. All the patients were enjoined to spend as much time as possible in the open air in all weathers (except stormy); never to stay long in a room warmed by furnace heat unless there were also a fire burning in the chimney; always to have a window partly open in their sleeping rooms at night; to use a sponge bath daily, as cold as could be borne without chill or depression, of course followed by rubbing; to wear suitable, but not oppressive, underclothing of woolen summer and winter.

I attach much importance to the habit of fully inflating the lungs at regular intervals throughout the day (just before sitting down to meals, for instance), in order to stimulate the pulmonary circulation, especially of the apices, but I have found it very difficult to persuade patients to carry out this precept faithfully.

External irritation was employed in every case, with the usual analgetics, diet, etc.

## A DISEASE OF THE MAMMARY AREOLA PRECEDING CANCER OF THE MAMMARY GLANDS, PAGET'S DISEASE.<sup>1</sup>

BY C. B. PORTER, M. D.,

*Surgeon to the Massachusetts General Hospital.*

In the St. Bartholomew's Hospital Reports for 1874 Sir James Paget describes the disease, to a case of which I wish to direct the attention of the Society this evening. His description is so concise, and the article so short, that I cannot do better than to read it entire.<sup>2</sup>

I believe it has not yet been published that certain chronic affections of the skin of the nipple and areola are very often succeeded by the formation of scirrhus cancer in the mammary gland. I have seen about fifteen cases in which this has happened, and the events were in all of them so similar that one description may suffice.

The patients were all women, various in age from forty to sixty or more years, having in common nothing remarkable but their disease. In all of them the disease began as an eruption on the nipple and areola. In the majority it had the appearance of a florid, intensely red, raw surface, very finely granular, as if nearly the whole thickness of the epidermis were removed; like the surface of very acute diffuse eczema, or like that of an acute balanitis. From such a surface, on the whole or greater part of the nipple and areola, there was always copious, clear, yellowish, viscid exudation. The sensations were commonly tingling, itching, and burning, but the malady was never attended by disturbance of the general health. I have not seen this form of eruption extend beyond the areola, and only once have seen it pass into a deeper ulceration of the skin after the manner of a rodent ulcer.

In some of the cases the eruption has presented the characters of an ordinary chronic eczema, with minute vesications, succeeded by soft, moist, yellowish scabs or scales, and constant viscid exudation. In some it has been like psoriasis, dry, with a few white scales slowly desquamating; and in both these forms, especially in the psoriasis, I have seen the eruption spreading far beyond the areola in widening circles, or, with scattered blotches of redness, covering nearly the whole breast. I am not aware that in any of the cases which I have seen the eruption was different from what may be described as long-persistent eczema, or psoriasis, or by some other name, in treatises on diseases of the skin; and I believe that such cases sometimes occur on the breast, and after many months' duration are cured, or pass by, and are not followed by any other disease. But it has happened that in every case which I have been able to watch, cancer of the mammary gland has followed within at the most two years, and usually within one year. The eruption has resisted all the treatment, both local and general, that has been used, and has continued even after the affected part of the skin has been involved in the cancerous disease.

The formation of cancer has not in any case taken place first in the diseased part of the skin. It has always been in the substance of the mammary gland, beneath or not far from the diseased skin, and always with a clear interval of apparently healthy tissue.

In the cancers themselves, I have seen in these cases nothing peculiar. They have been various in

<sup>1</sup>—The fourth International Sanitary Congress will be held in Geneva, September 4th to 9th, and preparations have been made for a very full attendance.

<sup>1</sup> Read before the Boston Society for Medical Observation, April 17, 1882.

<sup>2</sup> St. Bartholomew's Hospital Reports, vol. x., page 87, 1874.

form; some acute, some chronic, the majority following an average course, and all tending to the same end; recurring if removed, affecting lymph glands and distant parts, showing nothing which might not be written in the ordinary history of cancer of the breast.

The single noteworthy fact found in all these cases is that which I have stated in the first sentence, and I think it deserves careful study. For the sequence of cancer after the chronic skin-disease is so frequent that it may be suspected of being a consequence, and must be always feared, and may be sometimes almost certainly foretold. I believe that a nearly similar sequence of events may be observed in other parts. I have seen a persistent "rawness" of the glans penis, like a long-enduring balanitis, followed after more than a year's duration by cancer of the substance of the glans. A chronic soreness or irritation (of whatever kind) on the surface of the lower lip often long precedes cancer in its substance; and, with a frequency surpassing all other cases of the kind, the superficial syphilitic diseases of the tongue are followed, and not superseded, by cancers which do not always appear to commence in a diseased part of the tongue.

For an explanation of these cases it may be suggested that a superficial disease induces in the structures beneath it, in the course of many months, such degeneracy as makes them apt to become the seats of cancer; and that this is chiefly likely to be observed in the cases of those structures which appear to be, naturally, most liable to cancer, as the mammary gland, the tongue, and the lower lip. One may suspect that similar surface-irritation has much to do with the frequency of cancer of the rectum, pylorus, and ileo-cæcal valve, in any of which parts the degeneracy, which might come naturally in old age and make them apt for cancer, may be hastened, and made prematurely sufficient, by an adjacent disturbance of nutrition.

In practice, the question must be sometimes raised whether a part, through whose disease or degeneracy cancer is very likely to be induced, should not be removed. In the member of a family in which cancer has frequently occurred, and who is at or beyond middle age, the risk is certainly very great that such an eruption on the areola as I have described will be followed within a year or two by cancer of the breast. Should not, then, the whole diseased portion of skin be destroyed or removed as soon as it appears incurable by milder means? I have had this done in two cases, but, I think, too late. Or, again, when one with a marked family liability to cancer has syphilitic disease of the mucous membrane of the tongue, with frequent recurrences of inflammation, should not all the worst pieces of the membrane be removed? I should certainly advise it, especially if the membrane were ichthyotic, if it were not that the disease is commonly so extensive that good scar-tissue would not be likely to be formed, and that bad scar-tissue, often irritable and ulcerating, is as likely to induce cancer as the syphilitic or ichthyotic patches would have been.

The case which I have to present was that of a woman about fifty years of age, of robust health, florid complexion, with delicate skin; in other respects healthy, with no hereditary tendencies. Two years previous to my seeing her she noticed, in her own words, "three little pimples like water blisters near the nipple of the right breast. There was no pain nor inconvenience from them and she gave them no attention."

Some months later, in hot weather, a moisture ex-

uded from the pimples and caused the clothing to stick to the breast and a constant desire to lift the undergarment from it. The disease increased very slowly by the eruption of new vesicles and became more troublesome. In about nine months it was accompanied by sharp pains in the nipple and occasionally shooting through the breast. I first saw her two weeks before operation, and about two years and two months from the first appearance of the disease. The affected surface was quite symmetrical and covered the areola and a considerable surface of the skin on its periphery. It presented a dry scaly appearance in some parts, and in others was covered with yellowish, soft moist scabs. On removing these the surface underneath was red and raw. Dotted about on the outer edge of the disease were minute vesicles, some covered with tiny, dry crusts. This condition was confined to the areola and its immediate neighborhood, and there was nothing abnormal about the rest of the skin. The nipple was strongly retracted, in fact depressed below the surface. The depression was filled with moist crusts, which, being washed away, showed the surface of the nipple, red, raw, and bleeding. There was a slight induration under and about the nipple, but the rest of the breast seemed normal to the touch. The pain was severe, at times of a stabbing, darting character. I advised immediate removal of the whole breast on the ground that the disease would probably result in cancer, if it were not that already. She accepted the operation at once. I removed the whole breast, which was quite voluminous with a wide margin of healthy skin around the nipple. The operation was done without the spray, otherwise with antiseptic precautions. The wound was washed out with a solution of thymol, one part to one thousand of water, and a drainage tube inserted. The dressing was eight thicknesses of cotton batting wet in same solution, and four more perfectly dry outside to afford elastic compression, all held in place by a swathe pinned tightly. The whole wound healed by first intention without a drop of pus. It is now nearly a year since the operation, and there is as yet no return of the disease.

The literature of the subject is meagre, though valuable papers upon the pathology of the disease have been published by Mr. Henry T. Butlin, in the *Medico-Chirurgical Transactions*, volume lix., page 107, and volume lx., page 153, and by Dr. George Thini, under the name of "Malignant Papillary Dermatitis of the Nipple, and the Breast Tumors with which it is found associated," in the *British Medical Journal*, May 14, 1881, page 760, and May 21, 1881, page 798. In his work on Tumors of the Mammary Gland Prof. S. W. Gross calls attention to eczema and psoriasis of the nipple. In the chapter on the *Ætiology*<sup>1</sup> of Neoplasms of the Mamma, he mentions two cases of cancer of the breast which had come under his observation, both preceded by long standing eczema. Dr. Thini's paper is based upon the microscopic examination of four breasts, in all of which cancer had followed upon so-called chronic eczema, but he seems to consider this a misnomer, and calls the disease malignant papillary dermatitis, and says: "In distinguishing, clinically, this malignant dermatitis from eczema, the chief points to be borne in mind are the well defined margin in the former, and the evidence, when the tissue is grasped between the fingers, of infiltration in the papillary layer. An eczema of the areola that had the

<sup>1</sup> *British Medical Journal*, May 21, 1881, page 801.

thickening and moist redness which have characterized some of the cases of this affection, would be so acute in its nature that the zone of inflammation would pass off gradually into the surrounding skin, would probably become wide-spread, and would give rise to very active symptoms. The overlapping margin forming a veritable ridge, with a sulcus behind it, which characterized another case, would of itself be sufficient to exclude the diagnosis of eczema. The history of the case may be found useful in establishing the diagnosis. In two cases which have come under my notice there was clear evidence that the disease began in a position corresponding to the openings of the lactiferous ducts, and remained limited in that position for some time before extending over the surface of the nipple."

Mr. Butlin reports the examination of four cases. The first two did not prove to be cancer, though both had been preceded by long standing eczema. The other two were both found to be carcinomata. One following upon eczema of only a fortnight's duration, the tumor being the size of a small egg, and reaching to within about half an inch of the diseased areola. His conclusions are as follows:—

(1.) That a certain relation existed between the eczema of the nipple and areola and the carcinoma of the breast.

(2.) That one of the first effects of the eczema was to produce proliferation of the mucous layer of the epidermis of the parts affected.

(3.) That in time the epithelium lining the galactophorous ducts became affected in like manner.

(4.) That the disease traveling along the large ducts reached the smaller ducts and acini, which became dilated and filled with proliferating epithelium, which was at length, so to speak, discharged into the surrounding tissues.

(5.) That the carcinoma thus formed was therefore essentially a disease of epithelium.

In the Clinical Society of London, May 27, 1881, Mr. George Lawson exhibited a cancerous breast following long standing eczema, the microscopic examination of which was made by Dr. Thin and included in his cases. At the same meeting Professor Lister reported a case which he had seen with eczema of nipple, and had contented himself with ordering the application of ointments only, and which he learned afterwards resulted in cancer of the breast.

If chronic eczema of the nipple can induce cancer of the breast, we need more careful observation and more definite data to determine at what point in the disease it is necessary to operate to avoid so serious a result. If, as Dr. Thin believes, the disease itself is a malignant dermatitis, or a form of epithelioma, it is desirable to be able to differentiate and so attack the disease with the knife at the outset.

Careful observation, and report of similar cases with microscopic examination, may ultimately lead to a grouping of appearances and symptoms that will make an accurate diagnosis possible.

#### REPORT OF EXAMINATION BY DR. A. T. CABOT.

The breast was little, if at all, enlarged, and contained no circumscribed swelling or thickening. The nipple and areola had disappeared, and in their place was a depressed, ulcerated surface covered with a scab.

On section through the breast the gland tissue seemed in about the same abundance as is usual in a person of

the patient's age, and did not differ noticeably in consistence from the normal. Immediately beneath the site of the nipple, however, there was an increased quantity of fibrous tissue extending down as a wedge into the breast beneath.

The breast was hardened in alcohol, and examined microscopically.

Sections through the depressed ulceration and the adjoining skin showed the following appearances: In the skin about, the papillæ were of the usual size and form. As the edge of the depression was reached, the papillæ abruptly changed their character, became much elongated, and were covered and surrounded by a greatly increased quantity of epithelium.

The subcutaneous cellular tissue was thickened, fibrous, and infiltrated with abundant small, round cells. The epithelium dipped down beneath its ordinary level; it was confined in the deep parts by the overgrown papillæ meeting over it, and in places had begun to form isolated alveoli in the neighboring tissues. No onion bodies were discovered.

The milk ducts running back from the site of the nipple towards the breast were often of normal size, and lined with a single layer of epithelium; others, on the other hand, were much dilated and packed with epithelium, while in their neighborhood were numerous nests of epithelial cells (cancer alveoli). The fibrous tissue was more abundant about these affected ducts, and richly infiltrated with fine, round cells.

The breast tissue at a distance of two inches from the site of the nipple showed a commencing carcinomatous degeneration. The gland acini were here and there largely dilated, irregular in shape, and stuffed full of cells, which in places were beginning to encroach on the surrounding tissues, and were forming in places true cancer alveoli in the parts about. Here, too, the same slight thickening of the fibrous tissue about was noticed, and its infiltration with small, round cells.

To recapitulate: The nipple was destroyed by a cancerous change resembling that seen in superficial cancer of the face. In many of the milk ducts was an abnormal growth of epithelium which had led to a carcinomatous infiltration of the surrounding parts, and in the breast itself were the typical appearances of a commencing carcinoma mammae.

#### RECENT PROGRESS IN DERMATOLOGY.<sup>2</sup>

BY GEORGE H. TILDEN, M. D.

##### MICROCOCCHI OF LUPUS.

For over a year past Max Schüllers<sup>3</sup> has examined lupus with especial reference to the presence of micrococci. The portions of diseased tissue in which micrococci are most easy of detection are the small, young nodules, which, embedded in the connective tissue, underlie and surround the larger and older centres of the disease. The freshly excised bits of tissue were placed immediately in a one per cent. solution of carbolic acid in water, in order to exclude any accidental access of micrococci. Sections of these made with a Roy freezing microtome, were colored in a one per cent. solution of methyl-violet in water, washed to remove excess of

<sup>2</sup> Concluded from page 392.

<sup>3</sup> Centralblatt für Chirurgie, Nov. 19, 1881, No. 46, page 1.

<sup>1</sup> Volume IX., page 160.

coloring matter, and put up in oil of cloves or glycerine. By this process only the cells and micrococci are colored blue, while the connective tissue remains uncolored. Powers of 660 and 1120 diameters were used, and Abbe's system of illumination with condensed artificial light. In the groups of round cells and single epithelioid cells which go to make up a lupus nodule, micrococci were seen situated between the cells, and also surrounding the individual groups of cells. From various points in the periphery of such a group of cells, rows of micrococci run out into the adjacent connective tissue, sometimes reaching as far as the next group of cells. As a rule the micrococci were not crowded together, but rather loosely distributed. In many specimens they were to be seen arranged around the large, nucleated epithelioid cells which lie scattered about in the neighborhood of the smaller lupus nodules. Each one of these large cells formed the centre of a group of micrococci, which sent out offshoots into the surrounding connective tissue. In regions where these large cells were more crowded together, it was not unusual to see rows of micrococci running from one cell to another, and when several of such rows met, at the points of intersection ensued small, star-shaped groups of micrococci. In the large and fully developed lupus nodules micrococci are very difficult of detection, by reason of the fact that the contained cells are very closely packed together. Nevertheless, in very thin sections, micrococci may be seen sparsely scattered about. They are invariably easy of demonstration at those points in the circumference of the larger lupus nodules, from which accumulations of cells extend in the form of long processes into the surrounding connective tissue. The free ends of such rows of cells are surrounded by groups of micrococci, which are also connected with the collections of micrococci belonging to the neighboring and smaller lupus nodules. Within the limits of diseased tissue micrococci were also found in the hyperplastic sebaceous glands, in the sheaths of the hairs around the coils of sweat glands, and occasionally in the walls of the smaller blood-vessels. In one case of superficial ulcerating lupus of the nose, micrococci were found in the epidermis between the hypertrophied papillae of the skin. The younger the lupus formation and the softer the surrounding tissue, that is, the less amount of cicatricial tissue present, the more abundant and the more distinct were the micrococci.

#### IODOFORM IN LUPUS.

Dr. Riehl<sup>1</sup> has used this drug as a local application in lupus vulgaris with flattering success. In order to remove the epidermis, and thus render the diseased tissue accessible to the action of iodoform, a fifty per cent. solution of caustic potash was applied to the skin after the removal of all dirt and grease from the same by means of washing with soap and water. Left in contact with the skin, a caustic solution of this strength in from one half to two minutes causes transparency, swelling, and detachment of the epidermis. This effect produced, the excess of caustic potash was washed off with water, the surface thoroughly dried, and a layer of finely powdered iodoform from one to two millimetres in thickness was applied to the surface which had been denuded of epidermis. This, covered with cotton batting, retained in place by strips of sticking plaster, was left undisturbed for from five to eight days. In no

case was there suppuration, and on removal of the dressing the iodoform was found embedded in the depressions formed by the disappearance of diseased tissue. Adherent at some points, at others, which were in process of cicatrization, the iodoform was merely superimposed. The sound skin between the points of pathological infiltration was pale and soft, and the general swelling and redness of the parts had in great measure diminished. In severer cases, while there was never suppuration, two or three successive applications of this dressing were required before the pathological infiltration of the tissues disappeared. The application of iodoform to surfaces of skin denuded of epidermis caused neither pain nor any disagreeable sensations. To do away with the pain necessary to the application of caustic potash local anesthesia may be used. The author has used this dressing in twenty cases of lupus, and always with good result.

#### MALIGNANT PAPILLARY DERMATITIS OF THE NIPPLE.

Dr. Thin<sup>2</sup> reports the microscopical appearances of four specimens of this lesion (known as Paget's disease). The microscopical examination of the skin proves that the disease is not eczema, but an inflammatory infiltration into the superficial layers of the cutis, combined with destruction of the connective tissue thereof, a destruction which never takes place in true eczema. In distinguishing clinically this malignant dermatitis from eczema, the chief points to be borne in mind are the well-defined margin of the former and the evidence to the touch of infiltration into the papillary layer of the skin. This malignant dermatitis has neither the symptoms nor the pathological anatomy of any hitherto-described skin disease. It is characterized by destruction of connective tissue and by permanence of the destructive process, for repair of the destroyed elements of tissue does not take place. The condition of things in the breast during the early stages of the disease, before any tumor can be felt, requires further investigation. In a case described by Mr. Butlin,<sup>3</sup> in which the breast was removed merely on account of the condition of the skin, the milk ducts for an inch or more beneath the nipple were found to be completely stuffed with epithelium. The breast tumors which follow this disease of the nipple are not the ordinary scirrhous or parenchymatous cancer of the breast, but are so-called "duct cancers," the fibro-carcinoma cysticum mammae of Waldeyer. In these cases the tendency of the growth is in round columns, which, as they grow larger, coalesce into round masses, the disposition to penetrate and infiltrate the interlobular connective tissue of the breast being but small. The growth of these tumors is regular, symmetrical, and centrifugal, and occasionally small cysts are formed by the breaking down of the cells contained in the central portions of the growth. The differences between these tumors and those usually known in England as adenomata are rather of degree than of kind. When an epithelial growth in the breast takes its origin in the epithelium of the milk ducts, if the development of columns and tubes (formed by reason of hyperplasia of duct epithelium) is localized and encapsulated by a growth of connective tissue, the tumor is an adenoma. If, on the contrary, there is progressive destruction of connective tissue and continued growth of the original tumor, the tumor

is a so-called "duct cancer," fibro-carcinoma cysticum mammae of Waldeyer.

POLYPAPILLOMA TROPICUM (FRAMBESIA, PIAN, YAWS).

Dr. Charlonis<sup>1</sup> has an interesting article upon this disease in the *Quarterly of Dermatology and Syphilis*. The malady is endemic in the East Indian Archipelago and in the West Indies. It begins with fever ushered in by a chill. The bodily temperature, which is normal in the morning, reaches 39° F. to 40° F. in the evening, the fever rarely lasting longer than fourteen days. Severe pain in the joints, both by day and by night, and lasting about three weeks, accompanies this initial fever. The joints affected are not swollen, but are very sensitive to pressure. About eight days after the first oncome of the fever appear gradually, here and there upon the body, papules about the size of the head of a pin, surmounted by a small yellow point. These papules are afterward surrounded by a dusky halo, and increase peripherically in size, reaching in some instances a diameter of three centimetres. They are flattened and of a papillary, fungous appearance, whence the name frambesia. Hard to the touch and movable only with the skin, they are covered with a honey-like, yellowish crust, upon the removal of which is seen a surface of papillary appearance, covered with a small quantity of white, sticky fluid. These tubercles may present themselves on any part of the body, head, or limbs, and by their coalition around the mouth and anus, on the penis and elsewhere, ensue larger, circular, and annular plaques. Mechanical irritation of these tubercles may cause long-standing and deep ulcerations. With the appearance of the skin manifestations comes swelling, painfulness, and sensitiveness of the lymphatic glands throughout the body. This condition of the glands gradually subsides, although for some time subsequent to the cure of the disease they may remain enlarged and hard. The disease is never fatal, the patients remaining in good general health notwithstanding the chronicity of the malady, which untreated may last for years. The pathology of the affection is essentially a localized dermatitis, characterized by accumulations of granulation cells, beginning around the smaller blood-vessels. Secondary changes are dilatation of the smaller blood-vessels, of the tubes of the sweat glands, hypertrophy of the papillae of the skin, of the sebaceous glands, and of the erectoris pilorum. Strange to say, the nutrition of the hairs is not interfered with, and even when the scalp is the seat of the local skin manifestations neither temporary nor permanent baldness ensues. The disease is contagious, being both auto and hetero inoculable, the point of infection being, as a rule, marked by an ulceration which runs the usual course of an ordinary local venereal ulcer (chancreoid). The contagium is fixed, and the period of incubation is from three to five months. Both the blood contained in and the pathological excretions from the tubercles are carriers of contagion, but retain this property only "in stadium incrementi et acmes" of the same, afterward becoming innocuous. The disease is chronic by reason of the continued appearance of new tubercles or groups of tubercles, the older ones meanwhile becoming dried up and disappearing without leaving any cicatrix. The prognosis is good, the malady being very amenable to

treatment, which consists in the local application of mercurial ointment to the lesions of the skin and the internal administration of iodide of potassium or iodoform. These latter benefit only the osteoscopic pains, and in no way influence the course of the tubercles. During the initial febrile stage quinine is given. The many notable points of resemblance between this disease and syphilis have led most observers to regard frambesia as a modified form of the latter, but the author has decided this point by inoculating two individuals suffering from frambesia with syphilis. In both the persons thus inoculated syphilis was developed and ran its usual course.

PEMPHIGOID AND ANTHRACOID ERUPTIONS DUE TO THE INGESTION OF IODIDE OF POTASH.<sup>2</sup>

In reporting a case of each of the above, Besnier takes occasion to remark upon the inaccuracy of the common opinion, that in cases of so-called medicinal eruptions the character of the skin manifestations is *always* determined by the drug administered. Another factor in many such instances is the individual idiosyncrasy of the patient. The resultant of these two factors, however, is constant, in other words, the same drug always produces the same variety of eruption in the same person. The common form of cutaneous lesion due to the ingestion of iodide of potash is papular and pustulo-papular, the so-called iodine acne, essentially alike in the majority of cases. Nevertheless, erythema, anthracoid or giant acne, resembling the acne seen in severe bromism, bullae and purpuric spots, may each be caused by iodide of potash in different individuals. Any one of these may also be produced by the bromides, by mercurials, salts of quinine, morphia, and atropia, and by salicylate of soda. The variety of results implies a difference in pathogenesis. In ordinary cases in the common acne due to iodide of potash for example, the eruption is very likely due to direct irritation of the skin, by reason of the elimination of the drug through the same; but in other instances, the cause is probably reflex irritation, the starting point of which is the intolerance of the stomach to the drug ingested. This is the more likely as Besnier has observed, in one instance, that the same drug which, taken by the mouth, produced morbid changes in the skin, when administered hypodermically to the same individual did not give rise to any cutaneous lesions whatever. The author also states that he has never seen any eruption upon the skin caused by the absorption of iodine when applied as a dressing to wounds, in the shape of iodoform.

— The following resolution was adopted by the St. Louis Medical Society, April 1, 1882:—

*Resolved*, That the St. Louis Medical Society, while it desires to accord the broadest freedom to medical investigation and recognizes fully the right of individuals to form and hold private opinions, hereby declares that it regards with disfavor any steps taken to lessen or obliterate the distinctions and safeguards between an honorable practice of medicine founded upon science and that founded upon any of the current delusions and exclusive medical systems of the day.

## Hospital Practice and Clinical Memoranda.

### SOLID TUMORS OF BOTH OVARIES.

BY GEORGE H. BIXBY, M. D., BOSTON,  
Surgeon to St. Elizabeth Hospital for Women.

By the kindness of Dr. Garceau, of Boston, Mrs. M. consulted me for an obscure abdominal enlargement. She brought from her family physician the following history:—

"Dear Doctor: I was called to see the bearer, who was suffering from an enlargement of the abdomen. The patient exhibited signs of great debility. I ordered iron, and occasionally diuretics. These remedies failing to arrest the daily increasing enlargement, I removed by paracentesis twelve quarts of dark-colored serum. I now found on palpation in the left ovarian region a smooth, spherical, and unyielding mass, the size of a fetal head. On making this discovery I directed the patient to see you."

My own records read thus: Mrs. M., native of Ireland, aged fifty-two, had been in this country a number of years. Above the medium stature, dark complexion, and prominent features, she looked haggard and careworn. The enlarged abdomen was apparent through the clothing, and she seemed with the greatest difficulty and discomfort to support her burden. Notwithstanding her immense size and weight, she informed me that she lived quite alone, on the third floor, attended personally to all her domestic affairs, and had even walked a distance of two miles that morning. There was no history of malignant disease in her family.

The catamenia first appeared at sixteen with normal type and duration. She married at twenty-two, and gave birth with normal birth and child-bed a year later. Shortly after this event conjugal disagreement necessitated a separation. The climacteric was reached at fifty-two without complication of any kind.

For years her occupation had been that of a cook among the higher classes. She first noticed her ailment eight months before, manifesting itself by a sensation of discomfort when in the right lateral position, and later, by the presence of a tumor in the right ovarian region. The growth began rapidly to increase in size, and the abdomen to enlarge generally. At the third month from the first discovery of the tumor, the distended abdomen interfered materially with respiration. On inspection the following conditions presented: Neck and shoulders emaciated, mamme atrophied, abdomen enormously enlarged with pendulous walls, lower portion of the same, pudenda and lower extremities highly oedematous. Girth of abdomen at umbilicus forty-six inches, six inches nearer the pubes fifty-five inches.

On deep pressure in the right ovarian region, a smooth regular mass was indistinctly made out, the relations of which, owing to the fullness of the abdominal and pelvic cavities, could not be accurately determined. Percussion showed universal flatness including flanks, with signs of fluctuation of which the wave was unbroken throughout. Auscultation showed heart and lungs unaffected. Vaginal exploration revealed the uterus in a condition of senile atrophy. Douglas's fossa impacted by a firm non-fluctuating mass. Rectal exploration confirmed the absence of fluctuation with more fullness at the left. Bimanual palpation showed

the tumor presenting in left ovarian region and that felt in Douglas's fossa to be the same. In view of the above history, namely, short duration (less than eight months), rapid accumulation after tapping, presence of blood in the serum, early oedema of the abdominal walls and pudenda, I was inclined to consider the case one of malignant disease of the ovaries.

An operation was suggested, but not urged at this late stage. Later, I saw the patient at her home with her family physician. On this occasion I found her in bed; she was suffering pain and difficulty of breathing from the great distention of the abdomen.

Dr. G. at once performed paracentesis, removing twelve quarts of dark-colored serum, the last third of which was mixed with blood. Immediate relief followed. Now the tumor at the left was found, upon palpation, to be the size of a fetal head, pediculated, and apparently free from adhesions. On deep pressure over the right ovarian region there presented an irregular mass the size of the fist; the latter admitted of slight motion in any direction, and seemed firmly attached to the right corner of the uterus.

From a later report I learned that the operation was followed by acute peritonitis, ending fatally on the fourth day.

Report of the post mortem twenty-five hours after death. Rigor mortis slight; general emaciation; abdomen distended with gas; walls oedematous. On section, abdominal and pelvic cavities contained considerable serum. Enlarging the opening in the direction of the pubes, there presented, in the left ovarian region, a round smooth mass, the size of a fetal head, free from adhesions, and traceable by a long slender pedicle to the left corner of the uterus. In the same region on the right an irregular mass the size of the fist. Upon section its tissue yielded readily to the edge of the scalpel. It consisted of a honey-comb arrangement of cysts, varying in size from a flax-seed to that of a ripe cherry. This arrangement extended from periphery to centre, throughout the whole mass, the larger ones being nearest to the centre. Of a round, uniform shape, they were made up of meshes of fibrous tissue, the interspaces of which were filled with material differing in color and consistence, some resembling calf's foot jelly, others cream.

The uterus in a condition of senile atrophy.

The tumor of the right side, round, or rather oblong in shape, was attached to the right corner of the uterus by a slender flat pedicle at least six inches in length; its surface showed no evidence of former adhesion. The same pathological conditions obtained as in the other specimen.

As regards the nature of this affection, it would seem from its duration, course, symptoms, and result, that we may have had to do with malignant disease.

Entertaining some doubt in regard to this question, while looking up the subject of ovarian pathology I was struck with the similarity of this case with one reported by Rindfleisch in his text book on Pathological Anatomy,<sup>1</sup> which I quote in full. Under the third form of ovarian cystoids, he says, "Both ovaries have equally advanced, in a certain form of cysts, and colloid degeneration. They have passed beyond the size of a man's fist; are smooth at the surface, and through the albuginea a large number of cysts, from the size of a millet seed to a cherry, are seen, which are all arranged side by side like a mosaic; upon

section we perceive that the mosaic of cysts extends throughout the thickness of the organ, in such manner, however, that the largest specimens, up to the size of a cherry, are found at the centre; the whole reminds us of a honey-comb.

"The contents of the cysts are throughout a clear jelly, so that in this ovarian cystoid, also, the name of ovarian colloid, which is particularly customary, in forms one and two, might be not unfittingly applied.

"Moreover, form three is very rare, and hence it probably comes that nothing certain is known of the origin of the cysts. The microscopic examination speaks decidedly in favor of the Graafian follicles; even the smallest cysts are not smaller than these; moreover, each cyst has a proper firm membrane, and finally the already mentioned arrangement of the cysts, the smaller without, the larger within, very strikingly reminds one of the same arrangement of the Graafian follicles. I would designate the degeneration as *Struma Ovarii* (according to Virchow's acceptance of *Struma*)."

As regards the indications for, or the propriety of, operative procedure in this form of ovarian disease (which one is strongly tempted to denominate semimalignant), my experience and observations show that at no distant day recurrence after operation with a more decided type of malignancy has been the rule. When an operation is contemplated, from the rapid yet insidious course of the affection, the patient is generally not impressed with the seriousness of her trouble until the opportune moment has passed.

## BOSTON CITY HOSPITAL.

CASES IN THE SERVICE OF DR. JOHN G. BLAKE.

REPORTED BY MR. H. B. WHITNEY.

### CASE I. SUDDEN PERICARDIAL EFFUSION.

M. W., a married woman, twenty-six years of age, was brought to the hospital on Monday, March 14th, at about 12 M. She was seen immediately by the house-physician, and gave the following history: Had been well until two weeks ago, when she was attacked with pain in the joints of lower extremities, without noticeable redness or swelling. Had some loss of appetite and other symptoms of febrile condition. Continued in this way until five days ago, when she was attacked with chills. These have been since repeated; but from their indefinite history it is doubtful if they were true rigors. Following the occurrence of chills her abdomen became swollen and tender; there was vomiting of green material, with constipation. Last catamenia occurred one week ago, last but one seven weeks ago. Nothing to be ascertained of a nature pointing to miscarriage. Has been no jaundice, no dyspnoea or swelling of feet, no sensation of weight or pressure in præcordia. Nothing unusual has been noticed in connection with micturition.

Patient appears on inspection to be comfortably sick. No cyanosis or especial dyspnoea. Abdomen moderately distended; no redness or swelling of joints. Tongue moist, covered with a thick white coat; slight oedema of lower extremities. Some tenderness on pressure over præcordia; apex beat very indistinct on palpation. Abdomen everywhere tympanitic, somewhat painful on deep pressure. Examination of lungs entirely negative. Relative dullness of heart begins at upper border of third left costal cartilage, and does

not extend beyond middle of sternum toward the right, or beyond apex toward the left. Heart sounds very indistinct and distant; no souffles; apex beat in normal situation.

Pulse 130, a little soft; temperature 103.4° F. Half an ounce of brandy was ordered every two hours, an abdominal poultice, diet restricted to milk and lime-water.

Patient was next seen at 4.30 P. M. Seemed much more comfortable, and made a statement to that effect. Pulse 143, but of better strength than before; temperature 104.2° F. No pain or dyspnoea; countenance brighter. No further physical examination made at this time.

At 6.30 P. M. house-physician was summoned in great haste, and found the patient in a moribund condition; respiration exceedingly embarrassed; face and extremities cyanotic; pulse small, feeble, very irregular and intermittent. Nurse stated that nothing had occurred to call attention to the patient previous to the time when house-officer was summoned. Two and one half grains of carbonate of ammonia were immediately given by subcutaneous injection, but without effect, patient living only a few moments.

The feebleness of the heart sounds at the first examination had given rise to a suspicion of pericarditis, and percussion was consequently practiced immediately after death. The upper limit of relative dullness was found to be at the second left costal cartilage, dullness extending on the right half an inch or so beyond the margin of the sternum. The pericardial sac was at once punctured with an ordinary subcutaneous syringe in the third left intercostal space, and several syringefuls of clear serum removed, position of body being on the back. No autopsy allowed.

### CASE II. ANEURISM OF THE INNOMINATE.

H. D., colored, forty-six years old, a jobber, entered the hospital March 5th with a history of only four weeks' sickness. Comrades state that for many years he has been very old, considered by many to be a little unsound. For past four weeks has had cough and loss of flesh. Was, however, perfectly able to keep at work until ten days ago, when suddenly, without unusual exertion, he lost his voice and got very short of breath. These symptoms have grown constantly worse up to the present time. Complains of no pain; says he has had none from the outset either in throat or thorax. Refers all his difficulty in breathing to the throat where he himself locates the obstacle to easy respiration. Never had any palpitation, but has been a little short of breath for two months. Feet have never been swollen to his knowledge. Has had no chill; sputum has been tough, but not noticeably reddish. Never had acute rheumatism; doubtful specific history.

Lips and nails are cyanotic. No marked emaciation; no oedema of extremities. Tongue readily protruded, is clean and moist. Mind clear. No pulsation at either wrist; but heart beats with fair strength, not weak enough, apparently, to account for absence of radial pulses; beats number 120 to the minute. Cannot talk above a whisper; breathing is excessively difficult; coughs and expectorates with great effort; sputum tough, of uniformly reddish tinge. Dyspnoea comes on in paroxysms, during which expiration is much prolonged; inspiration comparatively easy. In the intervals the difficulty seems to be chiefly with in-

spiration; and the loud sounds issuing from the larynx makes it seem as though there is some obstruction at that point. Respirations 31; lips buff, and alae nasi dilate with each expiration; temperature 100.4° F.

Nothing to be seen in throat with the aid of a spatula. Area of relative cardiac dullness not increased; no abnormal dullness on percussion over fronts; both contain sonorous and sibilant râles throughout. Heart sounds normal at apex; at base a soft systolic soufflé is heard over both second interspaces, near borders of sternum, propagated upward into carotids, in both of which a very distinct systolic soufflé is heard. Slight fullness of throat noticed, but not unilateral or such as to attract further notice. No marked pulsation of carotids, no thrill discovered at any point. Dullness over lower two thirds of right back; faint bronchial respiration; numerous fine, moist, and dry râles. Left back contains dry râles like the fronts; otherwise normal. No soufflés, pulsation, or thrill to be discovered behind.

Ordered whiskey, half an ounce, carbonate of ammonia five grains, every two hours. Nitrite of amyl, three drops, was given by inhalation, with some slight relief.

March 6th. Sweats profusely, but is much brighter and more comfortable; no pulse at either wrist; femoral pulse fair strength; same with the carotid, but none can be felt over either subclavian; small quantity of brown, tenacious sputum; tongue moist; pulse 130; temperature 99.6° F.; respirations 14. P. M. A faint pulsation is perceptible in the right radial artery. Urine: acid; high color; specific gravity 1020; slight trace of albumen; sediment not remarkable.

March 8th. Has continued about the same as at last record, but difficulty in breathing seems to be increasing, is more constant and less paroxysmal. Careful examination shows no further development of physical signs. Toward the latter part of the day the dyspnoea became more excessive, patient sank into a semi-conscious condition, and died at 9.30 P. M.

Autopsy, made by Drs. Cutler and Gannett, showed the following pathological changes in the lungs, heart, and great vessels, other organs being comparatively healthy:—

Right lung free; few old adhesions between lobes. Pleura opaque, thickened, injected. Covered with false membrane over whole lower and half the upper lobe: lower lobe oedematous, and in condition of red hepatization; upper lobe injected and oedematous. Bronchial glands enlarged, and considerably thickened. Bronchi filled with frothy, bloody serum.

Left lung free; anterior edge of upper lobe emphysematous; lower part of lower lobe somewhat oedematous and consolidated; smaller bronchial tubes slightly inflamed; upper lobe slightly oedematous and injected.

Pericardium contained a few centimetres of clear fluid. Heart enlarged laterally and vertically. Left ventricle contracted and empty, right ventricle and auricle moderately distended with a pale, soft, gelatinous, dark-red coagulum. Mitral opening admits tips of three fingers. Tricuspid valves not remarkable. Both right and left ventricles somewhat enlarged; walls of both thickened, especially the left. Muscular substance not remarkable.

In the aorta, above valves, were numerous thickened, opaque, yellow patches of calcified appearance. Opening of innominate admitted middle finger, which passed immediately into a sac, the size of a lemon, occupying the position of the innominate, a portion of

the carotid, and the right subclavian as far as the thyroïd axis. Thickness of wall of sac equal to that of normal aorta. Sac contained a red fibrin thrombus, nearly filling its cavity, adherent to half its inner wall. Opening of left carotid two millimetres in diameter; from here on carotid is the size of end of fourth finger. Opening of left subclavian entirely obliterated. Lumen of subclavian beyond this point reduced in size to that of normal radial. Walls three times their usual thickness. Aortal arch half again as large as usual, intima throughout showing numerous calcareous plates.

Trachea lay beneath sac above described, somewhat flattened out, admitting the little finger. Apparently no compression of œsophagus.

## Reports of Societies.

### PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

APRIL 24, 1882. Dr. Goss presided in place of Dr. Warren who was unable to be present.

#### PULMONARY CONSUMPTION.

Dr. F. MINOT read a paper entitled cases of Pulmonary Consumption followed by Recovery or by Arrest of the Disease.<sup>1</sup>

Dr. H. I. BOWDITCH said that he had seen cases similar to those reported by the reader, but that they were comparatively few in number. He could recall two or three cases whom he had examined six or eight years ago with the result of finding decided disease at the apices of the lungs, and who yet to-day were going about town apparently well, and engaged in active business.

It is well to go on with careful treatment even after the rational and physical signs of disease seem to have disappeared, for we frequently in these cases have the disease return. Dr. Bowditch then cited the case of a patient whom he had sent to Colorado with disease of the lung, and who after a year returned to Boston perfectly well, and was found on examination to present normal auscultation and percussion of the lungs. He resumed his work of a moulder, and in four months began to cough, lose strength, develop crackling under the clavicles, and is now a hopeless case of phthisis pulmonalis. The disease is so likely to lie dormant at the apices for a time, and then break out again under circumstances favoring its development, that patients in its early stages had not only better go away from Boston but stay away permanently.

Dr. Bowditch also remarked that the sea-coast from Cape Cod to Cape Sable, with its damp winds, was, as a rule, bad for consumptive patients; these patients should either go well out into the ocean, as to Block Island, or the Isles of Shoals, or far into the interior; this is of course not of so much importance further south. In answer to a question by Dr. Reynolds as to whether consumption had increased among the well-to-do classes during the last twenty-five years, and whether our present habits of living do not tend to lessen the tendency to phthisis pulmonalis, Dr. MINOT said that he thought that there were fewer cases, and that there was a very noticeable improvement in physique corresponding to the great improvement in living and dressing.

<sup>1</sup> Vide page 409 of this number of the JOURNAL.

DR. REYNOLDS spoke of the large number of people who wore flannels at the present time in comparison with those of twenty-five years ago; he also inquired as to the value of respirators in a climate like that of New England, as it seemed to him that a moderate protection would be good.

DR. BOWDITCH said that the difficulty was to make the patients use them; he had tried them forty years ago, and found that they kept the patients warmer, but did nothing towards a cure of the disease; he suggested that experiments with respirators charged with disinfectants might be useful, making the treatment continuous, and only removing the respirator at meal time.

DR. F. C. SHATTUCK said that antiseptics, especially carbolic acid, had been used in this way; also eucalyptol and creosote, and that much benefit had been attained by this treatment in gangrene of the lung. Dr. Shattuck also spoke of a remarkable increase in weight in a patient while the physical signs were decidedly advancing.

DR. MINOT remarked that in deciding whether we should send a consumptive patient to some other place rather than to the sea-shore, we should take into consideration other factors which are often of great importance in the individual case, namely, the dislike of the patient to go away from her family, great comfort at home, etc.

DR. BOWDITCH mentioned the case of a gentleman whom he examined ten years ago and who complained of cough and dyspnoea, but was the picture of health. A physical examination revealed explosions of crepitant râles under the left clavicle; these signs have continued ever since, and have gradually extended further down, with also a slight increase in the dyspnoea, but very slight cough and the general health is good.

#### SOLITARY KIDNEY.

DR. BOLLES presented a specimen of solitary left-sided kidney found in an old woman; there were two ureters, one of them lying unattached on the surface of the right psoas muscle. There was no renal fat on either side.

#### PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

C. M. JONES, M. D., SECRETARY.

MEETING April 17, 1882. DR. HAVEN presided.

DR. C. B. PORTER reported a case of

#### DISEASE OF THE MAMMARY AREOLA PRECEDING CANCER OF THE MAMMARY GLAND,

which is published in full on page 412.

DR. A. T. CABOT reported the microscopical appearances in the specimen.

DR. WILLIAMS asked if direct connection could be traced between the irritation of the skin and that in the areola.

DR. PORTER replied that there appears at first an irritation of the surface of the breast; that from this the epithelial disease extends into the ducts, and that it was still a question whether excision at the early period would stay the progress of the disease or not. It is difficult to diagnose in these cases between chronic eczema and the beginning stage of cancer of the breast. Paget holds that at the outset we have only eczema to

deal with, that this sets up an irritation which eventuates in cancerous degeneration. Only eight of the cases heretofore reported have been microscopically examined. The only guide for interference where the cancerous degeneration is not manifest is the duration. An eczema of the breast of long standing should be removed. He would consider it chronic after a year's duration, and advise excision.

DR. BOWDITCH thought that physicians generally did not recognize conditions like those described, or appreciate the possible result; that the idea of exciting an eczema of the breast, even if chronic, would seldom occur to them as necessary. In the case of such an eruption, if recovery did not ensue after treatment for a reasonable time, removal would seem advisable.

In answer to Dr. M. H. Richardson, DR. PORTER stated that the disease in this case began in three minute water blisters located in the areola near the nipple.

DR. RICHARDSON has at present under observation a case in which similar appearances exist on the summit of the nipple itself, and the induration and inclination to bleed in this case recall epithelioma of the lip.

In answer to Dr. Sabine, DR. PORTER said he did not know, in his case, how long retraction of the nipple had existed; and, further, in the cases already published there had been no statement of improvement of the eczematous condition under treatment. In his own case the patient thought she had at one time improved while under one treatment, and deplored not having begun the treatment earlier, but the apparent improvement was not maintained.

In reply to Dr. Jeffries, it was stated that there had at no time been any glandular enlargement, and none has occurred since. Further, if the operation is undertaken, no matter what the period, the whole breast should be excised. In two of Dr. Butlin's four cases in which the breasts were removed, no trace of cancerous disease was found. Mr. Lawson holds that all chronic eczema of the breast should be removed.

DR. A. T. CABOT stated that he had recently removed a breast whose nipple had appearances similar to those in Dr. Porter's case. The nipple had been affected in this case five years, and had disappeared, but the cancerous disease, though recent, was much farther advanced than in the case reported.

DR. F. W. DRAPER showed a

#### SPECIMEN OF RUPTURE OF THE HEART.

The subject was a nurse, sixty-four years old, able to do all ordinary work, who was found dead in bed, having evidently died without a struggle. The pericardium contained fourteen ounces of blood; the left ventricle was in systolic contraction, and posteriorly was found an external opening from the ventricle, about one half inch in length, the internal opening being a point located just below the auriculo-ventricular roof. The muscular fibres between were torn asunder, and in the course of the wound were blood clots. The heart was distinctly fatty degenerated, yellow mottled, and friable; the coronary arteries were atheromatous, also the thoracic and abdominal aorta. The position of the rupture towards the base and not at the apex was unusual. Attention was also called in the same case to a congenital anomaly, one of the kidneys having two ureters which united about half way towards the vesical opening.

DR. PORTER showed a

# KNEE-JOINT AND SECTION OF THE FEMUR FROM A CASE OF AMPUTATION AT THE HIP.

Disease had existed in the hip-joint for about two years, and in the knee for six months. Previous to operation there appeared to exist dorsal dislocation of the femur, as usual in hip disease, but degeneration and absorption of the head of the bone had taken place, and the end was found in the acetabulum. The position of the head with reference to the trochanter, nearly on a level with each other, suggested the possibility of an old impacted fracture, but the longitudinal section disproved this idea, as the cancellous tissue was found to be intact.

The knee was ulcerated, the joint filled with pus, the cartilages degenerated, and lifted from the underlying bone, and the head of the tibia was also involved in the general destruction.

## MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

At the last stated meeting of the Society, held April 24th, Dr. A. D. ROCKWELL read a paper entitled:—

### OBSERVATIONS ON HEMIPLEGIA, BASED ON EIGHTY-ONE RECORDED CASES, WITH SPECIAL REFERENCE TO CEREBRAL LOCALIZATION.

All the eighty-one cases, Dr. Rockwell said, had occurred in his own practice during the last fourteen or fifteen years. Of course the symptoms, and groupings of symptoms, varied very widely in hemiplegia on account of the different parts of the brain that might be affected. He first related a typical case, in which the patient, after suddenly becoming partially unconscious, was found to be suffering from hemiplegia, facial paralysis, and some aphasia. The aphasia disappeared altogether in the course of two weeks, and, as was usually the case, the paralysis of the upper extremity disappeared much less rapidly than that of the lower. In fact, the patient never fully recovered the use of the arm.

The anatomical or regional diagnosis was made of an effusion of moderate extent in the vicinity of the corpus striatum. A second attack, two years after the first, proved fatal. Eighteen of the eighty-one cases were of very similar character to this.

In Dr. Rockwell's cases the rule was found to be carried out, that right hemiplegia preponderates, and it had occurred to him that the reason why in right hemiplegia aphasia was apt to continue for a short time and then disappear was, that the great majority of persons were probably left-brained, just as they were right-handed. When, therefore, there was a lesion affecting the speech-centres of the left hemisphere, those of the right hemisphere had to be educated in the same manner as was necessary in the case of the left hand when any accident occurred to the right. The right side was so little exercised that it was incapable of action until this "education" had been acquired. Sometimes the hemiplegia was of very short duration, while the aphasia persisted. In one patient, aged fifty-three, who came under Dr. Rockwell's care, the paralysis (of the right side) had recovered in a few days after its appearance, but the aphasia had remained for a very considerable time. After a month's treatment, by means of central galvanization, there was very marked improvement.

When there was increased temperature, with swelling of the parts paralyzed, the optic thalamus was sup-

posed to be involved in the cerebral lesion, and Dr. Rockwell mentioned one case in which the pons varolii and the crus cerebri were believed to be affected. The evidence of the former being involved was, increased temperature and emotional demonstrations on the part of the patient, and of the latter, a paralysis of the third nerve, as indicated by ptosis, dilated pupil, and external squint. As an instance of the cortical substance of the brain being the seat of lesion, the case of a physician was mentioned in which the patient suffered for several days from intense pain in the head, when he became unconscious, and complete hemiplegia, with aphasia, resulted. Recovery from the hemiplegia was very rapid, it having quite disappeared by the end of five days; but the aphasia persisted longer. At the present time, four years after the attack, he seemed to be perfectly well, with the exception of slight aphasia. He exhibited marked amnesic symptoms in writing however, and he generally had great difficulty in understanding what he read himself, while if another read to him there was no trouble of this kind.

In all the cases that had thus far been referred to, Dr. Rockwell said it was presumed that there was either rupture or occlusion of the blood-vessels. There was a third cause which operated more rarely, indeed, but which he thought should not be lost sight of, namely, spasm of the vessels. In one case of this character the patient had several attacks of hemiplegia, from which he recovered after a short time, but at last there came one of so great severity that it proved fatal. The autopsy showed that there was no injury or occlusion of vessels whatever, although there were other abnormal conditions found in the brain, the nature of which was not stated. The concluding portion of the paper was devoted to the affection of the special senses in hemiplegia, and in this connection Dr. Rockwell expressed the opinion that the special senses were independent of the hemispheres. In hemiplegia the sight was not infrequently more or less affected, but this was much more rarely the case in regard to the hearing.

An unusual case was related in which the patient suffered for several years from epileptiform convulsive seizures, repeated from time to time, and at last was attacked with hemiplegia accompanied with complete loss of sight. This had continued for some time when he came under Dr. Rockwell's observations, and the extraordinary part of the case was that complete recovery from this total blindness was instantaneously accomplished by means of the application of a powerful induction current. He had no doubt, however, that the recovery would have occurred spontaneously in the course of time, as he regarded the loss of sight as purely functional. The strong reflex stimulation afforded by the electric current had simply hastened this result.

At the conclusion of the paper Dr. SEGIN, being called on by the chair, remarked that the blindness in connection with hemiplegia to which Dr. Rockwell had referred, while it was of great importance clinically, was not really of positive value from the fact that no ophthalmic examination was made in the cases. In the statement that the special senses were not connected with the hemispheres he believed that Dr. Rockwell was in error, since evidence by experiments and observations was all the time accumulating which tended to establish this connection. Especially was this true in regard to sight; and he had himself known of four cases of hemiopia in man. With respect to audition, while the evidence was conclusive in the

case of experiments upon animals, this was not so as regards man. Dr. Seguin then referred to a peculiar case of aphasia accompanied with impairment of audition, from which the patient never recovered, occurring in a well-known physician of New York. He could always distinguish and understand two or three words or simple sentences spoken to him, but any long, connected discourse was, as he expressed it, "all Greek" to him. The same was true of any new or unaccustomed terms with which he was not familiar. When he died the third frontal convulsion was seen to be perfectly healthy; while the lesion was found in the upper part of the parietal lobe—there being an area of softening in this locality which approximated the areas supposed to govern the special senses.

After a few concluding remarks by Dr. ROCKWELL, the next business of the evening was taken up, which was the reading of a report on

#### CALCIUM SULPHIDE AS AN ANTISUPPURATIVE,

by DR. ANDREW H. SMITH, president of the Therapeutical Society.

(To be concluded.)

### Recent Literature.

*A Practical Treatise on the Diseases of Children.* By J. FORSYTH MEIGS, M. D., and WILLIAM PEPPER, M. D. Seventh Edition, revised and enlarged. Philadelphia: P. Blakiston, Son & Co. (successors to Lindsay & Blakiston). 1882.

A noticeable change in the arrangement of this work, the last edition of which appeared in 1877, is a separate article on Food, which was very much needed for the completeness of the book as a whole, in former editions this subject having been treated incidentally in connection with the causes and management of thrush.

The important subject of the different average amounts of foods to be given at different ages is thoroughly treated and practical rules laid down for the frequency of its administration, rendered all the more valuable from the varied and wide experience which one of the authors at least has had for the last thirty years among a class of patients where observations on this most difficult and vital branch of the subject can be studied with presumably the best results, as they have been a class who, both from cultivation and means, were willing and able to carry out minutely the difficult details laid down by a beloved and respected family friend as well as practitioner.

It will be well for those physicians who are inclined to rely on condensed milk as the proper food for infants to carefully read that portion of the article on Food which is devoted to this preparation, as it is a very sensible and fair exposition of the subject, bringing out strongly the point that while in the early weeks of infancy it may be used as a useful substitute where good cows' milk cannot be obtained, owing to its approaching very nearly the much diluted milk adapted to that age, yet for the older infant, where a less diluted milk is required, the amount of sugar in the condensed milk becomes so greatly in excess of what nature has provided in mother's milk, that it must necessarily interfere with the infant's nutrition, making fat babies rather than muscular, hardy ones.

While willingly accepting the authors' opinions as

results of long experience, and as supported by the most recent chemical and physiological investigations, we would suggest that it is not by citing individual cases and giving general rules alone that the intelligent student of the infant's digestive organs is aided in the best way, for the failures which he inevitably must meet in treating his cases by exactly the same methods spoken of by the authors arise from the great variety of factors which enter into the problem of regulating the individual infant's digestion, and he would find of equal if not greater value the principles of chemistry and physiology, on which the authors' deductions are based, in aiding him to treat understandingly a large number of cases. The important investigations showing the rôle which the fats play in the infant's digestion, the careful analysis of the dyspeptic stools of breast and cow-fed infants made by Herz and others, might be very well cited in support of the very sensible views expounded by the authors, and without taking up much additional space.

A few words, if but of warning, about the numerous farinaceous foods so commonly used by the laity and recommended by physicians, would be of great service in advancing the success of artificial feeding, from the mere fact of their being laid down in a book of such wide-spread circulation in our community as the one before us. We have been unable to find even the word farinaceous in this edition, although it appeared in the sixth in the article on Thrush.

Although it is stated on page 918 that the authors have accepted the classification of skin diseases made by the American Dermatological Association in 1878, yet when various skin diseases are spoken of they are not classed under their proper headings, eczema, for instance, being placed under vesicular diseases of the skin, while the classification accepted makes eczema as much an erythematous and pustular disease as a vesicular. The nomenclature is, however, a great improvement on that of the last edition.

An entirely new article on Rôtheln has been incorporated in the text, embodying the latest views and knowledge of this disease. It is, considering the great variety of opinions which have been brought forward as to the characteristic symptoms of rôtheln, about as concise and satisfactory a description of the disease as has yet appeared in print. The elaborate table on the relative mortality of croup and diphtheria has been brought up to the year 1880.

*Note on the Microscopic Appearances Presented by the Blood of Scarletina and Typhoid Fever.* By J. H. KIDDER, Surgeon, U. S. Navy. (With six Photographic Illustrations.) Washington: Office of the Surgeon-General of the Navy. 1882. Two pages.

In this note the author describes the appearances observed in the blood from a child twelve years old, who was ill with scarlatina for twelve days, and from a case of typhoid fever terminating fatally on the seventeenth day.

The peculiar appearances on the fourth day of scarlatina were "the increase in the number of leucocytes, numerous granules of varying size and corresponding to the color of the red corpuscles of the blood; thin and blue like coagula, within which the red corpuscles shrunk away from the leucocytes and arranged themselves in a compressed row upon the margin of the clot

very similar to the arrangement of columnar epithelium, and very minute spherical, highly refracting, globules of a vinous red color attached to the leucocytes."

In the blood from typhoid fever, taken upon the fifteenth day of the disease, "the leucocytes were but little if at all increased in number and did not present the shining red globules of scarlatina. For the most part they did not differ materially from the leucocytes of healthy blood, but here and there one was found containing ill defined opaque spherules mostly within the substance of the leucocytes, and neither colored nor highly refractive. These bodies bear a closer resemblance to micrococci than those found in scarlatina blood."

In neither case, however, does the author consider that these "globules" and "spherules" are micrococci, but inclines rather to the opinion that they are due to some form of fatty degeneration, as has been observed in the blood of yellow fever.

The blood was examined after first drying a thin layer which was subsequently stained with methyl violet or iodine. Koch has lately shown that this method is not always to be relied upon in detecting the presence of bacteria in blood, as the coagulated albuminous material often prevents the staining fluids from acting upon the organisms. His method is to subject the film of blood for some time to a heat of 140° Cent., then to stain with methyl blue (which does not have a tendency to overstain as in the case of methyl violet), and finally wash off the superfluous blue with distilled water. It is suggested, also, that in the proper use of osmic acid there would be a means of determining the fatty nature of the globules.

The micro-photographs are remarkably clear, and show the great advantage of this method of depicting such minute bodies.

*Lectures on the Pathological Anatomy of the Nervous System. Diseases of the Spinal Cord.* By J. M. CHARCOT. Translated from the reports by Dr. E. BRISSAND, in the *Progrès Médicale* by CORNELIUS G. COMEGYS, M. D. With illustrations. Cincinnati: Peter G. Thomson. 1881. xi, and 165 pages.

It is scarcely necessary to commend the writings of Charcot, or the reports of his lectures. Dr. Comegys has done a service in giving these lectures to the profession in English; they are not only of interest theoretically, they have also a practical bearing, and will aid to an understanding of diseases of the spinal cord.

There is given first a brief, but very clear, outline of the normal course of the columns of the cord, the pyramidal tracts being followed into the centrum ovale of the hemispheres and even to the cortex. The study of these tracts would not be complete without the aid given by a careful study of secondary degenerations affecting these columns, hence six or seven lectures are devoted to that subject.

Lecture twelve is devoted to a consideration of "foot phenomenon" and "tendinous reflexions." The latter is considered a spinal reflex, and the reasons therefor are given at length. In the next lecture is considered tardy contractions. "To sum up, gentlemen, the contracture of hemiplegia is not a passive rigidity. It responds, on the contrary, to a state of muscular activity. It is, doubtless, a phenomenon comparable to a normal contraction; only it is a durable, permanent contraction." By the use of a microphone his interns have shown that in muscles affected with this contracture

there is a constant interchange of contraction and relaxation in the fibres, "whilst the muscles in normal contraction produce a regular, sonorous, rolling sound constant in the number of its vibrations; the contracted muscle produces only a dull, heavy, irregular sound, with the interruptions and resumptions, or, in other terms, intermittent in character. It seems, then, patent, that here the muscular fibres follow each other in contraction, and relieve each other unceasingly."

The translation is not quite so good as might be. There are many instances of a transfer of French idioms into English, or the use of words in awkward connections which might have been avoided. The optic thalamus is also called the "optic bed" and the "optic couch." The "gray couches of the cortex cerebri" are spoken of. "*Fasciculi cerebelli directi*" is rather a hybrid expression. "Moieté" is several times used where "half" would be better. "Pyramidal direct" and "pyramidal crossed" may be good French order, but in English we usually speak of the direct pyramidal fasciculi, etc.

"On account of a coincidence which cannot be fortuitous, they are truly in the antero-lateral columns, the same crossed and direct pyramidal fasciculi that disease sometimes attacks separately." "I wish to attempt to show you that certain documents drawn from normal anatomy, allow us to recognize as many distinct parts, anatomically and physiologically, the same regions that pathological anatomy and the clinic have already placed in relief." These two quotations may serve as examples of a lack of clearness which is noticed much too frequently.

These are, however, only slight defects, and do not detract from the value of the book to the student and practitioner. We can commend it to the attention of all who desire to be familiar with the pathological anatomy of the spinal cord and with some of the phenomena of its diseases.

— Judge Brady, of New York, has refused to grant the application for a new trial for William Sindram, the murderer of Mrs. Crave, which was made recently under the statute passed for his especial benefit. Judge Brady said he had in the interest of the prisoner entirely disregarded the objections to the application for a new trial, which would be valid in an ordinary case, and which in strictness would be valid in this case. Against all the theories of experts the plain fact remained that Mrs. Crave, a moment before the shooting, was in apparently good health, and was attending to her ordinary duties. No one of the experts had pretended to affirm that the wound she received had no part in her death. The doctrine of the law was that if a person by unlawful violence injure a person having a dangerous bodily infirmity, this infirmity shall not become a shield for the evil doer. If the death be accelerated by the injury, the person inflicting it must be held responsible for the death; otherwise the weak and infirm would be deprived of the protection which they in a peculiar degree need. In regard to the statement that Mrs. Crave's medical treatment had not been as skillful as it ought to have been, Judge Brady said that a malefactor who creates the necessity of a physician's science could not be permitted to take advantage of the unskillful treatment of the victim, except in very extraordinary cases.

# Medical and Surgical Journal.

THURSDAY, MAY 4, 1882.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year including postage.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.* HOUGHTON, MIFFLIN AND COMPANY,  
No. 4 PARK STREET, BOSTON, MASS.

## THE NEW STATE-PRISON AT CONCORD, MASSACHUSETTS.

The old State-Prison at Charlestown, built in 1805, was enlarged and remodeled from time to time until 1874, when the necessity of confining more prisoners than it could properly accommodate led to a consideration of the question of removal to a new spot. Although the location of the prison had been carefully chosen for its sanitary advantages, the recent discharge of a vast quantity of offensive sewage in its immediate vicinity had made the air of one wing extremely offensive. The increase in crime had necessitated the crowding of 683 convicts into a space designed for 652, and the north wing, constructed in 1829, with 304 cells of only 171½ cubic feet each, opening by grated doors into a corridor containing 139,840 cubic feet, was so disgracefully foul after having been occupied over night, that much serious illness resulted therefrom. The ventilation of the other two wings was defective, but the air-space to each convict was sufficient. The external walls of the prison could properly contain 500 convicts, 183 less than the actual number within them, while accommodation was thought to be needed for 800.

There were three plans suggested to overcome the difficulties in the way: first, to build a new prison large enough for 800 convicts; second, to enlarge and remodel the old prison for the same number; third, to put the old prison in proper order for 500 convicts, and to build a new prison for 300.

The last, and by far the best, plan would have involved a remedy for the stinking sewage spread out on the flats, improvement in the ventilation of the south and west wings, and rebuilding the north wing so as to make it contain only one half as many cells as before. The second plan was open to the objection that there was not sufficient available space for carrying it out. The first was chosen as in the end not likely to cost any more than the third, and as being more consistent with the views of prison discipline on the part of those in power.

The place chosen for the new prison was not the best, on sanitary grounds, but still without serious objection if the original plan had been adhered to of getting a pure supply of water from a pond not far distant. On the contrary, the surface water is taken from the sluggish Concord River or from superficial wells, with the sewage rudely spread on the neighboring flat, sandy land. The internal drainage, to say nothing of the water-closet in each cell, and the venti-

lation were originally very bad. In spite of poor water to drink, and vitiated air to sleep in, the health of the prison has been very good indeed, a fact which may be explained by the skill of the surgeon in charge, the toughness of the prisoners, or the natural salubrity of the situation.

The question now arises in the reflective legislative mind, after having spent over a million dollars on the prison, whether or not to spend seventy-five thousand dollars more for a pure water supply and faultless plumbing. With the economical aspect of the question we naturally have no familiarity, but an abandonment of the present prison on sanitary grounds is simply absurd, and any sort of condemnation of it for the same reason implies only the censure of evils which may be easily remedied by spending money. If from the reckless waste of money and unsatisfactory result in this prison and in the Worcester and Danvers insane asylums the State learns the obvious lesson, the experience, although dearly bought, may be of use in the future.

## ORGANIZED RAILROAD SURGERY.

PUBLIC notice has repeatedly been called of late to the necessity of properly providing for the care of the victims of accidents in civil life. Public ambulances and St. John guilds have sprung up here and there on both sides of the Atlantic, policemen and firemen are being taught in various places how to give the first aid to the wounded, and leaders in the daily papers have called attention to the good work. In this connection a mention of the organization of the corps of railroad surgeons of the Wabash, St. Louis, and Pacific Railroad Company may not be out of place. A little pamphlet, recently received, calls attention to the organization, and gives an account of what is claimed to be the first formal meeting of railroad surgeons ever held. This is by no means the first attempt made by a railway company to establish a surgical service; probably most lines of any extent have some sort of relation with various surgeons along their routes. It is simply claimed for it that it is the first time in which any body of surgeons ever met as forming a distinct surgical railway service organized as such.

The pamphlet alluded to contains two addresses by the Chief Surgeon, on the Organization of Railway Surgery, and on the Transportation of the Wounded. In the first is given an outline of the origin and growth of the service, and the general attitude of the employing company towards its wounded employees and its medical officers. The writer states the position of the company, that legally it is responsible for but few of the injuries received, and that it is neither legally nor logically under obligation to render aid. The object of the system is to secure the best service for those the corporation desires to aid, and to act in such a manner that the arrangement may not grow into an imposition, but be carried out at such a limited expense that on the whole nothing would be lost to the organization, and possibly a gain made by se-

curing the higher regard of the employees, who would feel that an interest was taken in their welfare that would prompt them to greater care and effort in matters pertaining to the welfare of the employing corporation.

The service has evidently been, to a certain extent, the surgeon-in-chief believes, a success, in that it has not grown, during the seven years of its existence, into the feared imposition, and has gained the confidence of the employees, securing to the unfortunates among them the best surgical science, at the same time affording the surgeons, as a whole, more remuneration for their work than they would have obtained had they done the same in the ordinary way. The employees have not been slow to learn that men who are expecting and hold themselves prepared for this special duty are none the less careful, and are, because of their assumed responsibility, more ready with appliances in greater perfection than those who are otherwise wholly engaged. In the same direction, and of vital importance alike to the employer, the patient, and the surgeon, lies the fact that familiarity with this class of work leads to better results than could otherwise be expected. In railroad surgery, as in other branches, especial attention and especial experience is of inestimable value.

Ever since the organization of the corps it has received the most cordial support of the management of the road. Their desire has been to deal with the utmost kindness and generosity toward the injured within the limit of business possibilities. They have only demanded that the case be deserving, the work well done, and the expense kept within the limits of business endurance.

In the second address some rather crude, as their author calls them, but at the same time valuable, suggestions are made in relation to the handling and transporting of those who are injured. The suggestions are not numerous, but well worth bringing to the attention of any body of men who are liable to have the care of the victims of railway casualties. They relate specially to the proper use of the stretcher, and the employment of ordinary cars as ambulances. Though fully alive to the advantages of properly constructed appliances, the author falls back upon the true surgical principle of taking what is at hand and making of it a bed in "which a patient with crushed legs, arms, or ribs, or suffering from concussion, can be placed easily, and on which he can ride without detriment." "Railroading is a civil service, but it smacks strongly of the military, and all concerned seem to acquire its spirit, and expect what pertains to it," and these suggestions as to surgical uses of railroad carriages and their appliances remind one curiously of the directions for the transformation of a soldier's weapons into implements for his own care when wounded.

The addresses are interesting, not merely from the humanitarian and economic stand-point, but from the suggestion of a possible branch of surgery as distinct as military surgery, which may grow up from the changed relations of the present day. The literature

of the subject is sure to be voluminous, and when the peace congresses of our time shall have made Ballingall and Longmore of interest only to the antiquarian, and the Military History of the War has been relegated to the trunk-maker and the upper shelves of the library, military surgery will, after all, only be replaced by volumes on railroad surgery and civil service emergencies.

#### JUDGE ALDRICH'S DECISION IN A SUIT FOR MALPRACTICE.

STOWELL *versus* DRs. SMITH AND FOX.

THE decision of the judge in a suit for damages for malpractice against two physicians, which was recently tried in the Superior Court at Lowell, Massachusetts, was accompanied by a just and clear statement of the rights and duties of the profession in its relations to the public.

We have frequently had occasion to call attention to instances in which members of our profession have been wantonly and maliciously subjected to annoyance, anxiety, and expense, by ignorant or unscrupulous patients bringing suits for malpractice, for all of which a tardy verdict of acquittal even is but a poor compensation. So long as no penalty exists for bringing idle suits of this character, and so long as both respectable lawyers and disreputable patients consider physicians fair game in this respect, the only available defense of the medical profession consists in giving the widest possible publicity to rulings such as that recently delivered by Judge Aldrich at Lowell.

The case in which suit was brought is typical of many others, and was briefly as follows: The plaintiff, a woman, broke a needle in a joint of one of her fingers, and after allowing it to remain there several days she consulted a physician at his office, who made a slight incision and withdrew the piece of needle. In three days she returned with the finger somewhat inflamed. The physician requested the patient to return the following day; instead of doing so, however, she consulted another physician, remaining under his care about two weeks, during which time the finger was lanced several times. Subsequently the patient repaired to the hospital and came under the care of the first physician. After some days she became impatient, left the hospital of her own accord, and sought the services of a third physician. After the lapse of two months the finger was healed though its usefulness was impaired. The woman then brought suit against the two first physicians, Drs. Smith and Fox, for \$5000 damages each, claiming that the cutting of the finger, probing the wound, and the application of poisonous carbolic acid highly intensified by boiled linseed oil, showed a want of skill on the part of the defendants.

Judge Aldrich, in announcing his decision for the defendants, began by reading the law governing such cases: that an honorable physician does not guarantee a cure, nor a lawyer insure a verdict; they only undertake to give their patient or clients their best judgment, skill, and care. And even then they are not bound

to exercise the highest skill of the profession to which they belong, but only the ordinary, average skill and care of men in like business in the same locality. As to this particular case on trial, he had deemed it of much importance, for it was a serious matter when professional men of good standing in the community were brought into court charged with ignorance and neglect of duty. For this reason he felt it his duty not to dismiss the case lightly with the simple statement that the plaintiff had failed to prove her case; nor did he wish the impression left that there was an almost even balancing of the evidence with a slight preponderance in favor of the defendants. A stronger vindication was needed, and he felt it his duty to say that his decision must be governed not by the rhetoric of the counsel, but by the facts in the case, and that there was absolutely no evidence showing that these physicians were unskillful, or did not exercise proper care. The fact that this finger finally got well under the care of another physician was no evidence of want of skill or care on the part of the defendants. There was a natural progress in diseases, and while at the commencement they were aggravated from day to day, there came a time, a crisis, when they ended in a destruction of the tissues, or the healing process began. And it was too often the case that thoughtless persons improperly gave the credit of the cure to the last physician in attendance, or to the last medicine administered.

The evidence in the case showed that the entrance of the needle into the joint was an adequate cause for the result; that the plaintiff did not follow the instructions of the defendants; that the healing process began before leaving their care; and that the physicians used all necessary care and skill in their treatment of the finger.

#### BORO-GLYCERID AN ANTISEPTIC COMPOUND.

A PAPER was recently read before the Society of Arts, in London, by Professor Barff, describing his antiseptic compound, boro-glycerid ( $C_3 H_5 Bo_2$ ). Specimens of preserved food were shown from Jamaica, the Falkland Islands, Zanzibar, and other distant places, the freshness of color, taste, and aroma of which are said to have been remarkably perfect. Oysters opened since last September, and kept in an open jar, gave entire satisfaction, as did fresh turtle, lobsters, cream, eggs, beef, mutton, etc., which were shown both raw and cooked. The length of time these edibles had been kept varied from three to twelve months.

If we are not mistaken an attempt was made three or four years ago to introduce this same compound, or one extremely like it, into practical use in this country, but it was unsuccessful, owing to a difficulty about a patent or some other similar impediments. Professor Barff seems to have convinced the Society of Arts of the value of his compound, and we hope may have perfected it to such a degree as to be able to carry the general public with him.

The cost is insignificant, the expense of treating fifty pounds of meat and fish being only about two shillings. Many other uses, besides those connected with domestic economy, immediately suggest themselves for such a compound, if fulfilling the promises made for it. What a boon to both surgeon and patient a tasteless, inodorous, unirritating, inexpensive antiseptic would be!

#### BOSTON LYING-IN HOSPITAL.

THE Annual Report for 1881 has just been received. The year's record shows a constant increase in the number of patients, while the proportion of unworthy applicants is steadily lessening. By far the larger number of those confined are admitted free, and this fact, combined with the increased expenses, has compelled the Trustees to appeal in their report for pecuniary aid. Unless such assistance is rendered, the Trustees will be obliged to reduce the running expenses by rejecting the applications of many of those who, by reason of their poverty, are most in need of help.

During the year the hospital has frequently received patients at the request of the Dispensary physicians who suddenly found themselves called upon to attend some poor woman in quarters utterly unfit for such purposes. An Out-patient Department has been opened, by which medical attendance at their homes is furnished during confinement to all women residing within the limits of the city proper, who are unable to pay for such services. This new departure has been found to fill a gap which the medical profession has long felt existed. It is to be hoped that the appeal soon to be made to the public will obtain a liberal response.

#### MEDICAL NOTES.

— The Hampden District Medical Society had their annual meeting Tuesday, April 18th, with an attendance of about forty. The present system of child-birth reports were unfavorably regarded, and one doctor suggested that physicians in general would live up to the law better if it was so framed as to be of real service for census purposes. For instance, the law might require the registration of the sex and nationality of the child. Dr. Stebbins read an interesting paper on Diseases Incident to School Life. Dr. J. W. Hannum read a paper on Disease Germs; and these officers were chosen: President, S. W. Bowles; Vice-President, G. S. Stebbins; Secretary, Treasurer, and Librarian, G. C. McClean; Committee on Trials, Dr. J. H. Waterman, of Westfield; Censors, Drs. Sanford Lawton, F. W. Chapin, David Clark, and M. Calkins, of Springfield, and A. F. Reed, of Holyoke; Councilors, Drs. T. F. Breck, G. C. McClean, L. S. Brooks, and M. Calkins, of Springfield, F. F. Dole, of Chicopee, and D. H. Nutting, of Chicopee; Committee on Ethics, Drs. T. F. Breck, T. L. Chapman, and J. W. Hannum; Delegates to the American Medical Association, Drs. Lawton, Calkins, S. D. Brooks, W.

G. Breck, of Springfield, and J. J. O'Connor, of Holyoke; Reporter, L. S. Brooks; Councilor of Nominating Committee, T. F. Breck.

— One of our exchanges says that "one cow's milk" may be worse than the mixed article, as proven by a case in which a baby fed on the milk of one cow sickened and died of tubercular disease, the cow itself dying two months later of tuberculosis. Had the milk of that cow been mixed with the milk obtained from a dozen others, the child would not have received daily such large doses of the diseased milk, and might have lived.

— At the annual meeting of the Middlesex North District Medical Society the following officers were chosen for the ensuing year: President, Charles Dutton, Tyngsboro'; Vice-President, William Bass; Secretary, George C. Osgood; Treasurer, N. B. Edwards, North Chelmsford; Librarian, William B. Jackson; Commissioner of Trials, Nathan Allen; Councilors, Charles Dutton, George E. Pinkham, Francis C. Plunkett, Franklin Nickerson, Cyrus M. Fisk, Samuel W. Fletcher, Pepperell; Lorenzo S. Fox, Hermon J. Smith, Moses G. Parker; District Nominating Committee, George E. Pinkham; Censors, John C. Irish, F. W. Chadbourne, Leonard Huntress, Jr., John J. Colton, T. Pierpont Shaw; Reporter, William H. Lathrop, Tewksbury.

A vote of thanks was tendered George E. Pinkham, the retiring president, for his faithful, impartial, and valuable services. The president and secretary were authorized to secure a permanent place of meeting. The following resolution was unanimously adopted:—

Voted, While we tender our sympathy to the family of our late associate, Dr. Abner W. Buttrick, in their affliction, and deplore the loss occasioned to the Society by his death, we recall, with pride and admiration, the traits of character to which his excellence as a man and physician was due. He had a mind analytic, observing, unusually clear and well-balanced, with a breadth of view that had been enlarged by foreign travel, a heart easily moved by human woes, a genuineness of purpose and sturdy common sense that frowned on charlatanism, whether in religion, politics, society, or the practice of medicine, a quiet heroism and calm philosophy which, rendered prominent by a long and trying illness, touched that illness with a gentle pathos and made the closing scenes of his life seem less like a bed of sickness than an impressive triumph over suffering.

The following delegates were chosen to the annual meeting of the American Medical Association to be held in St. Paul, Minnesota, commencing June 6th: M. G. Parker, C. A. Savory, Lorenzo S. Fox, Harvey Knight, George E. Pinkham, J. H. Eaton, W. T. Carolin.

Dr. Allen made suitable remarks regarding the death of Dr. George Stearns of Groton. Dr. E. Hyde read a long but interesting paper on The Germ Theory of Disease. A discussion of it was reserved till the next meeting. The following essayists were appointed for the next meeting: Drs. Irish, Jackson, Jefferson, and Kimball.

After the business of the meeting had been transacted an excellent supper was discussed in one of the rooms on the second floor, and an hour or two was passed in a very agreeable manner.

— At the annual meeting of the Suffolk District Medical Society, held on Saturday evening, April 29th, the following officers were chosen: President, Richard M. Hodges; Vice-President, J. C. White; Secretary, H. C. Haven; Treasurer, E. M. Buckingham; Librarian, B. J. Jeffries; Reporter, F. H. Williams; Commissioner of Trials, Charles W. Swan; District Nominating Committee, George C. Shattuck; Committee of Supervision, Benjamin S. Shaw, Samuel A. Green; Committee on Social Meetings, Calvin Stevens, George W. Gay, H. I. Bowditch, W. S. Dennett; Censors, W. H. Boardman, E. G. Cutler, A. N. Blodgett, T. M. Rotch, F. C. Shattuck; Councilors, S. L. Abbot, James Ayer, H. I. A. Beach, H. J. Bigelow, C. J. Blake, J. G. Blake, H. I. Bowditch, S. Cabot, D. W. Cheever, Hall Curtis, H. Derby, O. W. Doe, F. W. Draper, Thomas Dwight, C. Ellis, R. H. Fitz, C. F. Folsom, J. O. Green, S. A. Green, F. B. Greenough, W. H. Hastings, D. H. Hayden, R. M. Hodges, C. D. Homans, John Homans, W. Ingalls, B. J. Jeffries, F. I. Knight, S. W. Langmaid, G. H. Lyman, F. Minot, C. B. Porter, John P. Reynolds, W. L. Richardson, G. C. Shattuck, B. S. Shaw, A. D. Sinclair, D. H. Storer, A. M. Sumner, C. W. Swan, G. G. Tarbell, O. F. Wadsworth, J. C. Warren, Thomas Waterman, James C. White, E. A. Whittier, W. G. Wheeler, H. W. Williams.

#### NEW YORK.

— At a meeting of the Academy of Medicine, held April 20th, Dr. W. M. Chamberlain exhibited some of the uses of rubber tubing in the application of cold and heat to various parts of the body, to which he first called the attention of the profession in a paper read before the Medical Journal Association in the year 1874. He was led to make this second demonstration in view of the fact that within the past year the Leiter coils of metallic tubing have been introduced from Vienna as a novelty. The rubber tubing he claimed to be much superior, on account of its greater flexibility and smaller cost, and he believed that he was fairly entitled to the priority in suggesting this ready and efficient method of applying heat and cold to all parts of the body. The paper of the evening was by Dr. J. D. Bryant, Professor of Anatomy in Bellevue Hospital Medical College, and was entitled Peristoleal Preservation in Amputations of the Leg, illustrated by Specimens.

— The resignations of the eight members of the post-graduate faculty of the University Medical School were tendered on the 5th of April, with the request that they should take effect on the 20th of May, when the spring course of lectures terminates at the college; but in view of the fact that the dean of the regular faculty, in an interview with a reporter of one of the daily papers, made use of language in connection with their action which they regarded as disrespectful and uncalled for, and as the statements alleged to have been made by the dean have not been publicly contradicted, they have all insisted on their resignations being accepted at once, and have notified the faculty that they would not complete their courses of lectures. Dr. Roosa was the first to adopt this course, and Dr. H.

Knapp has now been appointed professor of ophthalmology in his place.

It seems now that the gentlemen thus resigning are in negotiation with the authorities of Cornell University, at Ithaca, for the establishment of a medical department in New York. If the present plans should be carried out, however, it will not be merely a post-graduate school, but a regular medical college, requiring an entrance examination and a three years' graded course, with an examination at the end of each; and it is the design to secure such an endowment for the new institution that the professors shall be independent of the students' fees.

—Dr. G. B. Taylor, inspector of vaccination, has reported to the Board of Health that 61,988 persons were vaccinated by the officers of his bureau during the year 1881. Of these 13,628 were in the public schools, and 8,039 were inmates of public institutions. In only 148 cases were there complaints of bad results following vaccination, and in 58 it was found that the trouble was caused by other diseases, while no deaths at all resulted from vaccination. During the year 1342 cases of small-pox were reported, and there were 404 deaths from the disease. Of the entire number of persons who suffered from small-pox 439 had never been vaccinated, while of those who died 122 had been vaccinated and 267 had not.

—Dr. Frederick R. Sturgis, president of the County Medical Society, has begun suit on behalf of the Society against the United States Medical College (eclectic) of New York to annul its charter, and to recover fines for its illegal issuing of diplomas and other abuses. The board of censors of the County Society has been satisfied for a long time that this college was engaged in fraudulent practices, and it has now ascertained that the institution was illegally organized. A law of the State, passed in 1853, provides for the organization of medical colleges by the Board of Regents of the State University, and requires that there shall be a paid-up capital of \$50,000. The United States College, however, was organized under a law of 1848 providing for the incorporation of manufacturing companies. It was opened in 1878, and since then has graduated a large number of students.

#### PHILADELPHIA.

—An outbreak of trichinosis occurred a short time ago in a German family keeping a hotel at Bridesburg from eating infected ham. The mother is dead, the father and two young children are very ill, and hopes are scarcely entertained of their recovery, a third child, and two of the neighbors, were less severely affected, but are still very sick. The fatal ham was only about half cooked, and a close inspection of its cut-surface, even without a microscope, showed the presence of the parasite in immense numbers. A section of muscular tissue obtained from the lady who died revealed living trichinae.

—During the compounding of a prescription in Frankfort, one of the outskirts of the city, an explosion occurred which severely burned the hands and face of the proprietor of the store who was compounding

the medicine, and also seriously injured a by-stander. The formula, which was intended to be used as a mouth wash, called for an ounce each of tannic acid and chlorate of potash. The druggist carefully powdered them separately, but on mixing the tannin with the chlorate the explosion occurred.

—An interesting surgical operation was performed recently by Dr. William A. Forbes, Demonstrator of Anatomy at Jefferson College. An eminent pianist of this city had an increasing difficulty in flexing the ring finger in performing. Dr. Forbes suggested the dividing of the tendinous slip which runs on each side to the little finger and to the third finger, from the tendon of common extensor running to the ring finger. This operation was performed subcutaneously, and a rapid cure resulted. The patient expresses great delight at the unusual freedom of motion given to the affected finger, and he is now able to use it with ease and comfort in his brilliant performances on the piano.

#### ST. LOUIS.

—A College for the Instruction of Medical Practitioners has been inaugurated in St. Louis, with the avowed object of teaching the special branches of medicine and surgery. There will be twelve departments, so arranged that special courses may be taken with as little loss of time as possible. Full particulars with regard to the time that special courses may be taken, the kind of clinics, the terms, etc., will soon be ready.

### DISSECLAMP.

#### EXHIBIT OF SURGICAL APPLIANCES AT NEXT MEETING OF MASSACHUSETTS MEDICAL SOCIETY.

An exhibit of surgical appliances will be held at Horticultural Hall at the time of the annual meeting of the Massachusetts Medical Society. No sale of articles or advertisement of such sale will be permitted.

Any member of the Society having articles of proved value which he may be ready to loan, will oblige the committee by communicating with them before May 30th. The committee consists of A. T. Cabot, M. D., 11 Park Square, and E. H. Bradford, M. D., 150 Boylston Street.

#### UNUSUAL RESULTS OF VACCINATION.

MR. EDITOR.—I have noticed in several numbers of your JOURNAL recently reports of eruptions simulating variola or varioloid following vaccination, and having had in my practice this winter two such cases, thought possibly they might be of interest.

I made during December, 1881, and January and February, 1882, one hundred and thirty vaccinations, of which I have a record, and in that number two presented the symptoms spoken of in the reports referred to above. One was a married woman, about forty years, who told me when I vaccinated her that she was subject to attacks of erysipelas, which I supposed to be some other cutaneous eruption, as nearly all such are called erysipelas among the ignorant here, a notion

encouraged by many irregular practitioners and traveling quacks, into whose hands such people frequently fall.

This case was vaccinated with a point of animal vaccine from Codman and Shurtleff, of Boston. The eruption appeared within twenty-four hours after the arm began to show any considerable inflammation, and covered the whole body so thickly that the point of a pencil could hardly be put down on normal skin. It took the shape of a small vesicle, never passing into the pustular form; these dried up in a few days, leaving dark-colored crusts, which separated in a week or ten days, leaving a slight dusky hue to the skin, which lasted several weeks.

The other case was in a boy, about twelve years old, and was similar in nature to the first, except that he had probably taken a slight cold, as he exposed himself hunting rabbits in the snow. This case was vaccinated with a point obtained from Cleveland, Ohio. Both cases exhibited some little constitutional disturbance, though not more than is frequently seen in a good vaccination. There was some general malaise, and some headache, but no pain in the back of consequence, and only slight fever.

I vaccinated five others in the same family with the first case, but *not* the woman's children, with points from the same package, without any eruption; and in the second, two others, brothers of the boy, also with points from same package, with no eruption. All these vaccinations took naturally and well. I have had several cases where there was an eruption of several small vesicles, over the inflamed areola of the arm, some distance from the points where the virus was inserted, but only these two where it affected the whole body. I have kept a record of all my vaccinations for several years, and have about two hundred on my list, in which I have noted the kind of virus used, whether animal or humanized, whether vaccination was primary or secondary, and whether successful or failure. One case I will detail, as it illustrated remarkably the protective influence of vaccination.

Some years ago I was called, one Friday, to see a patient at a boarding-house. I found a case of small-pox, the eruption already partially umbilicated. On Saturday he was removed to a tent, his room-mate going with him as nurse, and on Sunday morning I vaccinated the nurse, who, about the last of the week, had complained of backache and pain in the head, but by the next day his vaccination inflamed, and went through the regular course of vaccine disease, and he had no further signs of small-pox, though he stayed two weeks longer nursing the patient, a bad case of confluent small-pox, until he died, and assisted in burying him. Yours very truly,

JAMES L. QUINN, M. D.

EATON, OHIO, April, 1882.

#### PHYSICAL EDUCATION OF GIRLS.

It is very satisfactory to note that, in the course of the progress of the movement for the higher education of girls, a wise attention is being directed, in influential quarters, to their physical education. At a recent school congress, Miss Müller, a member of the London School Board, directed attention, in happy and energetic language, to the still prevalent neglect of physical exercises in our girls' schools. "It generally happens," she said, "that, if we walk into a playground, the boys

during their playtime are in full swing; one or two of the masters are half joining in and half directing the fun; there is scrambling, and laughing, and running, and shouting, and no thought of anything but play. All this is very good for the lungs and the muscles, and makes the blood circulate freely. But in the girls' playground we see groups of feeble, languid girls dawdling about. Sometimes the swings are locked up during play-hours, because the teacher considers it 'unladylike' for girls to swing. . . . The elastic movements of a graceful woman, the buoyancy of her step, and the dignity of her bearing, are the result, not of lessons on deportment, but of much free and unchecked activity in youth. The girl who can ride and skate and walk is the one who forms and retains a graceful figure, not the one whose only idea of locomotion is to walk with self-conscious stiffness for a quarter of a mile along a paved street." We are glad to see that, in the first number of the *Girton Magazine*, just issued, great stress is laid upon the value of the tennis-court as part of the collegiate system in the education of girls, and on the cultivation generally of physical exercises, which are, it appears, vigorously and vivaciously pursued at Girton. At the recent exhibition of hygienic dress held in London, under the auspices of the National Health Society, which attracted crowds of fashionable ladies, one of the most useful stalls was contributed from Girton, and the Girton corset was especially noticeable as a well-devised tribute to the laws of physiology applied to dress. M. Bert lately said shrewdly, "When you educate a boy, you perhaps educate a man; when you educate a girl, you are laying the foundation for the education of a family." This is as true physically as it is morally and mentally, and too much stress cannot be laid upon the importance of physical education and recreation in girls' schools.—*British Medical Journal*.

#### THREE CASES OF POISONING BY STRAMONIUM.

Cases of poisoning by stramonium are by no means common, but, apart from this fact, it is interesting to trace the accident by which these persons were poisoned with it. On March 19th I was summoned to a house where three members of a family (mother, daughter, and granddaughter), who had been quite well up to the time of having dinner, were soon afterwards seized with symptoms of poisoning, apparently by belladonna. I found on inquiry that they had had for dinner broth, with dried herbs in it, and also some beef, with turnips, carrots, and potatoes. In about ten minutes after taking the broth, and before rising from the table, they began to feel uncomfortable symptoms, these differing in each case. The mother felt her head first affected, the daughter her throat, and the child her stomach, causing nausea and vomiting. These symptoms supervened much more quickly than is usually experienced in poisoning by belladonna. As they had eaten nothing else for dinner besides what I have mentioned, it seemed hard to understand how they had been poisoned. I, however, obtained the remainder of the dried herbs, but there were only a few small pieces left. On adding boiling water, in order to make an infusion of them, the leaves expanded, and I found two unmistakable portions of the leaf of the datura stramonium, also two of the characteristic buds of the

plant and the corolla of a flower. On filtering the solution I applied a few drops to my eye, and it rapidly and fully dilated the pupil, causing indistinctness of vision and loss of accommodative power, which lasted for forty-eight hours. A stramonium plant most probably had been growing amongst the herbs, and was unwittingly picked and dried with the rest. The following is a short record of the cases: Mrs. A., aged seventy, was quite unconscious when first seen, four hours after dinner; her pupils were widely dilated and insensible to light. Her lips were swollen and the lower one was of a purplish hue. She was quite unable to swallow. Her pulse was 90, soft, and compressible. There was complete loss of power in her lower extremities, accompanied by subsultus tendinum, but she was busy with her hands pecking at imaginary objects. She also had several convulsions. My stomach-pump, unfortunately, being out of order, I gave her a subcutaneous injection of one sixth of a grain of pilocarpine, followed by a similar one in a quarter of an hour. This produced free vomiting and perspiration. She then began to rally, and I left her after giving her a fourth of a grain of morphia in pill. She had a fair night, but was very giddy and weak next day, and unable to get up. Susan A., a daughter of the above, was in a less serious condition, being in a state of mirthful and busy delirium, and very restless. Her pupils were widely dilated, and her cheeks flushed. She was able to take an emetic, and her bowels had been very freely moved, four times since dinner. She complained much of her throat, also of headache and vertigo. Her first sensations of discomfort, she afterwards told me, were referable to her throat. She gradually improved, but her throat and the mucous membrane of her mouth were sore for several days after. The granddaughter, a child four and a half years old, appearing poorly and vomiting after dinner, was taken home, nearly a mile off, to which she walked, though wandering more or less in her mind. She then came under the care of another medical man, who found her very restless and suffering from illusions. She was able to swallow an emetic, which caused renewed vomiting, and she was then treated with small doses of opium, under which she gradually became quieter, and was nearly well on the following day. Morphia, physostigma, and pilocarpine are all physiological antidotes to belladonna and its allies, but if pilocarpine can be depended upon to cause free vomiting (physiologically) as in the above case, its value would be enhanced in such cases of poisoning. — H. COUPLAND TAYLOR, M. B., in *British Medical Journal* of April 15th.

#### NOTE ON A CASE OF PSEUDO-HYPERTROPHIC PARALYSIS (?): RECOVERY.

Dr. H. DONKIN, Senior Assistant Physician, Westminster Hospital, relates in the *British Medical Journal* the following interesting case:—

On the 19th of November last (1881), I saw a boy six years old among my out-patients at Westminster Hospital, whose mother stated that he had been "slow and inactive" for about five or six weeks previously, and that she had noticed that his calves and buttocks seemed larger than before. These facts were given spontaneously, not elicited by questions.

The boy stood with his legs wide apart, straddled

and swung from side to side as he slowly walked, fell down on attempting to walk quickly, and was unable to raise himself from the sitting posture without pressing on one of his knees, and previously turning round and sitting on all fours. There was protrusion of the abdomen, and a noteworthy degree of lordosis. On stripping him, it was obvious to me, and the students who were present that his calves and buttocks were remarkably large for a boy of his size. The skin, especially over the lower part of the body, was markedly mottled; and, after repeated trials, I failed to elicit the knee-jerk, except perhaps very slightly in the left leg. Knowing, however, how erroneous it often is to attach any value to the absence of this latter phenomenon in children, and the general want of knowledge about the importance of this symptom at all, I mention it only because, on the recovery of the boy, which is the excuse for this record, the knee-jerk was elicited in both legs with as much ease as could be expected in the case of a rather excitable child. There was not any obvious enlargement of the muscles of the upper extremity. But I was able on that day to make but an imperfect examination, and unfortunately postponed both the measurement of the girth of his calves and all further methods of inquiry. Owing to an unavoidable absence, I did not see the case again till January 7th, more than six weeks after the first visit. Then, to my surprise, beyond some waddling in walking, I noticed no symptoms of loss of power. The boy could run with ease, and raise himself from the ground in the ordinary manner, even without placing his hands on the floor. The calves still appeared to me to be somewhat large; but the mother, again spontaneously, observed that both the calves and buttocks had "got quite small again." There was no mottling of skin. On the 14th, I saw him again. He still waddled slightly in walking; and I again failed, as I had also on the 7th, to produce any knee-jerk after careful trial. The mother believed the child to be now quite well. On the 21st, I could detect nothing abnormal about the child or his movements, with the exception of the knee-jerk symptom. I saw him again on February 10th, when I did not examine him; and for the last time on March 11th, when I found the appearance of the body normal; the gait in no way altered; running performed with perfect ease; and the knee-jerk produced with tolerable readiness.

The treatment I ordered from the first was complete rest; the boy having previously been exercised by the mother, believing, as she did, that he was careless. For medicine, as he looked somewhat weakly and pale, although quite cheerful, I gave him our mixture of iron and nux vomica. This he discontinued taking on February 10th.

I am well aware that this is but an imperfect report of the case, and that the diagnosis may be open to question. Still there is enough to show that we may have to look out at least for a set of symptoms *simulating* the disease about which so much has been written and so little is known. And there would seem to be no reason in nature why there should not be some temporary affection of the nerve-centres (even if this disease be regarded as connected with changes in the cord) giving rise to transient symptoms, just as we have the same possibility hinted to us in the occurrence of other forms of recovering paralysis.

The author disclaims any probable connection between the drug treatment and the result.

## REPORTED MORTALITY FOR THE WEEK ENDING APRIL 22, 1882.

Deaths reported 2736 (no reports from Chicago, St. Louis, and Cleveland); 978 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 600, consumption 406, lung diseases 375, scarlet fever 142, diphtheria and croup 141, small-pox 75, typhoid fever 48, whooping-cough 42, measles 37, diarrheal diseases 30, malarial fevers 26, cerebro-spinal meningitis 25, puerperal fever 15, erysipelas 12, typhus fever seven. From *typhoid fever*, Philadelphia 19, New York five, Pittsburgh four, Boston and Baltimore three each, Brooklyn, Cincinnati, Buffalo, and Milwaukee two each, District of Columbia, New Haven, Lowell, Cambridge, Fall River, and Holyoke one each. From *whooping-cough*, New York 20, Brooklyn six, Charleston and Lowell three each, Boston and Buffalo two each, Baltimore, Cincinnati, District of Columbia, Pittsburgh, Nashville, and Salem one each. From *measles*, Brooklyn 10, Philadelphia nine, New York eight, Pittsburgh five, Buffalo three, Cincinnati two. From *diarrheal diseases*, New York 20, Buffalo four, Baltimore two, Brooklyn, Boston, District of Columbia, and Pittsburgh one each. From *malarial fevers*, New York and Brooklyn 10 each, Baltimore three, District of Columbia, Buffalo, Lowell one each. From *cerebro-spinal meningitis*, New York and Buffalo four each, Brooklyn and Boston two each, Philadelphia, Cincinnati, Pittsburgh, Milwaukee, New Haven, Nashville, Worcester, Cambridge, Fall River, Salem, Haverhill, Brockton, and Waltham one each. From *puerperal fever*, New York and Pittsburgh three each, Boston and Baltimore two each, Cincinnati, Milwaukee, New Haven, Somerville, and Quincy one each. From *erysipelas*, New York four, Brooklyn three, Philadelphia two, Boston, Cincinnati, and Providence one each. From *typhus fever*, Baltimore four, New York three.

Two hundred and two cases of small-pox were reported in Cincinnati, Pittsburgh 29, Baltimore 17, Brooklyn seven, Buffalo four, District of Columbia one; diphtheria 23 cases, scarlet fever 10, typhoid fever nine, in Boston; scarlet fever eight, and diphtheria three, in Milwaukee.

In 37 cities and towns of Massachusetts, with a population of 1,024,669 (population of the State 1,783,086), the total death-rate for the week was 21.36 against 22.26 and 22.83 for the previous two weeks.

For the week ending April 1st, in 173 German cities and towns, with an estimated population of 8,391,316, the death-rate was 27.8. Deaths reported 4492: under five 2182; pulmonary consumption 669, acute diseases of the respiratory organs 510, diphtheria and croup 224, diarrheal diseases 121, scarlet fever 95, whooping-cough 66, typhoid fever 47, measles and rubella 28, puerperal fever 25, small-pox (Königsberg, Memel, Bruthen two, Munich, Essen six, Eupen) 12, typhus fever (Thorin two, Memel, Grandenz, Bromberg two) six. The death-rates ranged from 16.7 in Bremen to 44.1 in Nuremberg; Königsberg 29.1; Breslau 35.6; Munich 37.9; Dresden 20.8; Berlin 25; Leipzig 18.3; Hamburg 25; Ilanover 23; Bremen 16.7; Cologne 29.8; Frankfurt a. M. 27.7.

In the 28 English towns, with an estimated population of 8,457,514, for the week ending April 8th, the death-rate was 22.3. Deaths reported 3620: acute diseases of the respiratory organs (London) 333, whooping-cough 202, measles 172, scarlet fever 68, fever 52, diarrhoea 44, diphtheria, 33, small-pox (London 14) 19. The death-rates ranged from 14.7 in Halifax to 31.5 in Plymouth; Sheffield 18.5; Birmingham 19.5; Bristol 21.1; London 21.4; Leeds 21.8; Liverpool 25.1; Manchester 29.1. In Edinburgh 22; Glasgow 25.1; Dublin 27.7.

For the week ending April 8th in the Swiss towns, population 479,934, there were 51 deaths from acute diseases of the respiratory organs, pulmonary consumption 46, diarrheal diseases 27, diphtheria and croup 12, whooping-cough three, scarlet and typhoid fever each two, puerperal fever one. The death-rates were, Geneva 27.1; Zurich 33; Basle 23.6; Berne 29.9.

The meteorological record for the week ending April 22d, in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the U. S. Signal Corps:—

| Date.            | Barom-eter. | Thermom-eter. |          |          |            | Relative Humidity. |             |       | Direction of Wind. |            |             | Velocity of Wind. |            |             | State of Weather. <sup>1</sup> |            |             | Rainfall.            |                   |

# OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM APRIL 22, 1882, TO APRIL 28, 1882.

MACS, L. M., captain and assistant surgeon. Having reported at these headquarters, will proceed to Fort Lewis, Colo., and report to the commanding officer for duty. S. O. 86, Department of the Missouri, April 24, 1882.

FOSTER, JOSEPH Y., captain and assistant surgeon. His leave of absence for one month, granted him in S. O. 32, Department of the South, March 14, 1882, extended one month, with permission to apply for a further extension of twenty days. S. O. 17, Military Division of the Atlantic, April 25, 1882.

GARDNER, J. DE B. W., captain and assistant surgeon. Telegraphic instructions of this date, assigning him to duty at Fort Huachuca, A. T., confirmed. S. O. 57, Department of Arizona, April 19, 1882.

GARDNER, EDWIN B., captain and assistant surgeon. Having reported at these headquarters, is assigned to temporary duty at Vancouver Barracks, Washington Ter. S. O. 50, Department of the Columbia, April 14, 1882.

SHUTTLER, R. W., captain and assistant surgeon. Granted leave of absence for three months from May 1, 1882. Relieved from duty in the office of the Surgeon-General, to take effect May 1, 1882, and upon expiration of his leave to report by letter to the Surgeon-General. S. O. 92, A. G. O., April 21, 1882.

ROBINSON, S. Q., captain and assistant surgeon. Having reported at these headquarters, is assigned to duty at Fort Spokane, Washington Ter. S. O. 50, C. S., Department of the Columbia.

THE SECTION FOR CLINICAL MEDICINE AND PATHOLOGY OF THE SUFFOLK DISTRICT MEDICAL SOCIETY will meet at 19 Boylston Place, on Saturday, May 6th, at 7.45 o'clock. The following papers will be presented: Dr. S. W. Langmaid, A Case of Intussusception, with Recovery. F. S. Billings, S. V., Plastic Experiments on the Stomach and Intestines. Ernest W. Bowditch, Esq., The Sanitary Aspect of Nalant, Mass. Dr. Morton Prince, Puerperal Apoplexy, with two Cases.

It is important that the meeting should open punctually at the time appointed. ALBRIK N. BLODGETT, Secretary.

OBSTETRIC AND GYNECOLOGICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.—A meeting will be held at 19 Boylston Place, on Thursday, May 4th, at eight p. m. The following papers will be presented: Two Cases of Puerperal Septicæmia, Dr. Francis Minot. Some Statistics and Observations concerning Laceration of the Cervix Uteri and its Treatment, Dr. F. H. Davenport. J. B. SWIFT, Secretary.

BOOKS AND PAMPHLETS RECEIVED.—Suicide: An Essay on Comparative Moral Statistics. By Henry Morell, M. D., Professor of Psychological Medicine in the Royal University, Turin. The original expressly revised and abridged by the au-

thor for the English version. New York: D. Appleton & Co. 1882. (The International Scientific Series.)

Quarterly Report of Medical Officers, United States Army, with their Stations and Duties, as reported to the Surgeon-General April 1, 1882, or at Date of last Report received at this Office. Washington: Surgeon-General's Office.

The Importance of introducing the Study of Hygiene into the Public and other Schools. Address on the Forty-Eighth Commencement Day, March 29, 1882, of the Medical Department of the University of Louisiana. By Stanford E. Chaille, M. D., Professor of Physiology, etc.

On Ovariotomy. By Thomas Keith, Esq., M. D., F. R. C. S. E. (Reprinted from the American Practitioner.)

Microscopical Examination of Water supplied by the City of Hartford. A Report to the Board of Water Commissioners. By William J. Lewis, M. D. Hartford. 1882.

Proceedings of Meetings held February 1, 1882, at New York and London, to express Sympathy with the Oppressed Jews in Russia. New York. 1882.

A Grave Defect in our Medical Education. By Charles Sedgwick Minot, S. B. S. D. (Reprint.)

Civilization in its Relation to the Decay of the Teeth. An Essay read before the International Medical Congress, August, 1881. By Norman W. Kingsley, M. D., S. D. S. New York: D. Appleton & Co.

Chronic Bronchitis, its Forms and Treatment. By J. Milner Fothergill, M. D. Edin. With Numerous Illustrations. New York: G. P. Putnam's Sons.

A Treatise on the Science and Practice of Medicine, or the Pathology and Therapeutics of Internal Diseases. By Alonzo B. Palmer, M. D., LL. D., Professor of Pathology and Practice of Medicine, and of Clinical Medicine in the University of Michigan, etc. New York: G. P. Putnam's Sons.

A Treatise on Diseases of the Eye. By Henry D. Noyes, A. M., M. D. New York: William Wood & Co. (Wood's Library of Standard Medical Authors.) 1881.

Sixty-Eighth Annual Report of the Trustees of the Massachusetts General Hospital. 1881.

Third Annual Report of the State Board of Health of Illinois, with the Official Register of Physicians and Midwives. 1882.

Transactions of the Rhode Island Medical Society. Vol. II. Part V. 1881.

On the Morbid Conditions of the Urine dependent upon Derangements of Digestion. By Charles Henry Raffe, M. A., M. D., Caius College, Cambridge, London: J. & A. Churchill. 1882.

Intermittent Spinal Paralysis of Malarial Origin. By V. P. Gibney, A. M., M. D., of the Hospital for the Ruptured and Crippled, New York. (Reprinted from the American Journal of Neurology and Psychiatry, Volume I, No. 1, 1882.)

The Incidental Effects of Drugs. A Pharmacological and Clinical Handbook. By Dr. H. Lewin, Assistant at the Pharmacological Institute of the University of Berlin. Translated by W. T. Alexander, M. D. New York: William Wood & Co. 1882.

De la Lithotritie rapide. Par le Dr. Reliquet, Lauréat de l'Institut, Ancien Interne des Hôpitaux de Paris, Vice-Président de la Société de Médecine de Paris, etc. Paris: Adrien Delahaye et Émile Legrosnier, Éditeurs. 1882.

## Original Articles.

A CASE OF ADDISON'S DISEASE WITH  
AUTOPSY.<sup>1</sup>

REPORTED BY HALL CURTIS, M. D.

THE following notes were given me by the patient's son, a medical student:—

Mr. J. B., fifty-four years old, had an attack of plenury about ten years ago and recovered well; with this exception he has been well and strong; weight about one hundred and eighty pounds. First began to complain about May 1, 1881, of exhaustion after rising in the morning and of difficulty in dressing himself, requiring frequent rests. For some little time previously he had not had much appetite and was probably losing flesh, though not marked at the time.

From May 1st till July 1st, he lost flesh rapidly, the greater part being lost during three or four weeks in May. During May had little or no appetite, and remained at home part of the time, although able to go down town occasionally (during March and April he had been very busy and frequently drove down town at 6.30 A. M., not getting back until dinner at six).

Was somewhat nervous and restless at night. The only prominent symptoms, loss of flesh and strength, and peculiar color, once or twice looked very yellow.

May 6th. Urine carefully examined. No albumen. Color normal; specific gravity 1015; sediment slight; reaction acid; uph. + u. n. cl. n. e. p.; ind.—a. p. n.; albumen absent; bile pigments absent; sugar absent; sediment, nothing abnormal; amount about 425 centimetres; no casts, bile, or sugar detected, amount in twenty-four hours about normal. Sometime in May Dr. Ellis saw him; after examination could discover nothing behind the anemia, and prescribed quinia and gentian. About June 1st came to the shore, and there remained at home most of the time, going in town occasionally. Took milk and all the nourishing food possible, and appetite improved somewhat, and also color. About July 5th, saw Dr. C. D. Homans at his office in town. Nothing new outwardly since Dr. Ellis saw him, no pain anywhere, no gastric symptoms, bowels regular, sleeps better than in May. July 25th. Urine examined again with negative result. Color normal; specific gravity 1011; odor normal; sediment slight; reaction acid; albumen very slight trace; bile pigments absent; sugar absent; sediment—very few hyaline casts, considerable number of spermatozoa, and in twenty-four hours 1650 centimetres (a little above normal); total amount of urea 29.37 grains. "Thought by Professor Wood of little moment." No cough, but no better, and able to make less exertion without fatigue. On slight exertion liable to a feeling of "faintness," but never lost consciousness. Dr. Homans prescribed iron, quinia, etc., as much food as possible, and some other suggestions were made.

On July 29th, as Dr. Homans considered him very sick, Dr. Edes saw him in consultation with Dr. Homans at the latter's office.

Thorough examination was made with no result as to diagnosis, though Dr. Edes suggested the possible existence of Addison's disease from the discoloration of the face.

Dr. Edes examined the blood and found, he said, not "an excessive degree of anemia." "I think the number of red globules was about four million to the cubic millimetre. (Normal five million.) There was not any deformity observed in their shape nor was there an excess of the white."

Since then he has not been away from home except a short distance to drive, and on the water. Taken Wyeth's vinum cibi et ferri cum cinchona and Fowler's solution. The latter proved too irritating and was omitted a week ago. Slight looseness of bowels occasionally. Saturday, August 20th, had diarrhea for first time, without pain; taking during day milk and lime water, and a little brandy.

During last two weeks has had less appetite and has again become restless at night, for which has taken bromide of potassium with some apparent relief.

Dr. Graham, at the suggestion of Dr. Homans, had treated him four times with massage. By his kindness I am able to read you extracts from his notes on the case.

August 13th. J. B. since May has lost twenty-five pounds in weight. His face has a grayish, tanned, sallow appearance, and but for the normal redness of his lips and tongue, one would also think he was anemic.

On awaking in the morning there is some stiffness of the legs in the usual easy semi-flexed position, so that it is with difficulty and discomfort that he extends them in bed before getting up, but after walking across the floor a few times this entirely disappears, and does not return during day.

He gets up regularly every morning in spite of the feeling of weakness, which is his most troublesome symptom, and which obliges him to lie down and rest once or twice while dressing himself. This feeling of weakness continues all the forenoon, growing less until he has his lunch about twelve or one o'clock, after which he is at his best, but still greatly below par. There has been no perspiration on his skin since last May.

There is at times slight thickness of speech and difficulty of articulation, but this is scarcely perceptible. . . . At the first application, on the 13th of August, the patient had forty minutes of massage, consisting of upward and circular friction, deep manipulation, and passive motion of the joints, the deep manipulation occupying about half the time of the whole procedure. The friction and passive motion about one fourth of the time. This was between eight and nine A. M. before his usual time of rising.

On the 15th, Dr. Graham learned that when he arose on the morning of the 13th, he had no feeling of stiffness in his legs, and that during the following days he had several times perspired naturally. On the 15th and 17th the patient again had massage applied in a similar manner, with a like result to the first application. Two days intervened before the fourth and last massage on the 20th. The patient quietly remarked that he thought an omission of the massage for two days was rather long, as he had missed the tonic and sedative effect of it.

The influence of massage in this case was marked in improving the capillary circulation and restoring the perspiratory function of the skin, and also in reawakening the muscles, nerves, and spinal cord to their normal function.

The diarrhea continued through Saturday, and on

<sup>1</sup> Read before the Section for Clinical Medicine and Pathology of the Suffolk District Medical Society, April 8, 1882.

Sunday, August 21st, he was seen by me for the first time. During the past thirty-six hours he had been troubled with frequent dejections, thin and yellowish, no blood or mucus, and without much pain (at this time there had been many cases of nausea, vomiting, and diarrhoea along the shore). He complained especially of flatulence and distention of stomach and abdomen, particularly in the course of the colon; the abdomen was retracted, but resonant over large intestine, and not tender. The hands and feet were quite cold. The face was quite dark, almost a copper color, with many purpuric spots and points. On the forehead were large, irregular patches of color of a deeper brown. The eyes were sunken, conjunctivae slightly congested, and with a tinge of yellow; under the eyes the pigment was nearly black. The deep color of face extended half way down the neck, gradually fading in depth of shade. The hands were quite dark, with spots and flecks of a deep chocolate color, ceasing abruptly just above wrists; the inside of the elbows showed a deposit of pigment, which was also very marked on the outer aspect of the joint.

Treatment consisted in a hot rectal douche three times a day, followed by starch and laudanum enema (fifteen drops to half an ounce), Hoffman's anodyne, one drachm three times a day, hot fomentations to abdomen, hot bottle to feet, claret, glass of milk with two teaspoons of lime-water every two hours.

Monday. Pulse 120; patient has had three dejections in past twenty-four hours; slept pretty well; abdominal flatulence relieved; now complains of distress and pain in left side from nipple to edge of ribs, which becomes worse towards morning, caused by the dilated stomach; frequent yawning; hands still cold; tongue clean, except at posterior part, and marked with deep, transverse furrows; nervous at times during night; hyperaesthesia of back, followed by flatulency. Before the flatulence became troublesome was much annoyed by severe itching over shoulders and back; this has not been spoken of since the distention.

Tuesday. Last night was very much disturbed by pain in left side of chest; relieved by Dover's powder and mustard paste; past twenty-four hours one dejection with scybala. R. *Zinci valerianatis*, one grain, every four hours at night; chloroform, one ounce, aqua, four ounces; teaspoonful when flatulence is troublesome. The teeth were prominent; the gums were retracted, unhealthy, with abundant dirty gray deposit of tartar. *A few lines from the junction of the mucous membrane and skin of each lip was a wavy line of black pigment following the lip curves*; pulse 120; temperature 100° F.; has dyspnoea at times in morning after exertion; no palpitation or cardiac distress; no headache; sight at times troublesome, with "black specks floating," always myopic; no cough; chest resonant, and respiration clear throughout; hyper-resonance begins two inches below left nipple, and extends half way to navel (stomachal distention); heart sounds feeble, distant, without souffle, apex beat just below nipple; liver dullness in mammary line normal; spleen not enlarged; abdominal aorta pulsating strongly along left side of umbilicus.

Wednesday, August 24th. Quiet day and night, three dejections after brandy and Apollinaris; one dejection this A. M. more natural; was very restless at three A. M.; was relieved by zinc; the flatulence, distention, and consequent nervousness were relieved by the zinc and chloroform; took food well; was on couch part of day,

also this morning; temperature yesterday evening and to-day 97° F.; pulse 120; hiccough at visit, accompanied by marked succussion in stomach; still complains of pain one inch below nipple; colon much less distended.

Thursday August 25th. Temperature 97.2° F. last night and this morning; pulse very rapid and feeble; patient dull, constantly yawning; mind quite clear; passed urine freely this morning; wandered a little early this morning, possibly from Dover's powder given at two A. M. (?)

Friday, August 26th. Yesterday quite restless, going often from bed to couch; took more milk and broth; no dejection yesterday, one this morning; no distress from abdominal or stomach distention; slight delirium; yesterday and last night not so strong; restlessness relieved by *zinci valerianate*, one grain, at six and eleven o'clock P. M.; last night temperature 98.3° F., to-day, A. M. 98.2° F.; pulse 112; yesterday erythema on nose and right ear, none to-day; now rational, but torpid; eyes often closed; tongue more coated; voice at times inaudible; extremities cold; pulse very feeble and compressible; abdomen generally tympanitic except at left of navel; stomach resonance begins at seventh rib; epigastrium depressed; left hypochondrium full.

Saturday, August 27th. Yesterday was very restless, picking at bedclothes; low, quiet delirium; took food freely; during night was especially restless, constantly sitting up, and wishing to leave bed; no relief from zinc; became quiet at one A. M., after bromide of potassium, twenty grains; one dejection past twenty-four hours; abdomen generally tympanitic and full; this morning the joints of legs were stiff, and he was unable to flex them; pulse feeble; voice weaker; arms cold nearly to elbows; feet and ankles cold; complexion darker; no albumen in urine.

Sunday, August 28th. Yesterday he passed a quiet day, taking nourishment freely, requiring no sedative; now decidedly weaker; pulse 128; respiration 32 to 36; intellect duller; voice very faint; one dejection since yesterday A. M.; mouth half open; tip of tongue dry and glazed; passed urine freely this morning; temperature in axilla last evening 98.3° F. Seven P. M. Has been quiet without complaint; delirium constant but quiet; temperature 99.3° F.; hands and arms abnormally warm; legs cold; pulse 130; respiration 40; eyes closed; pupils respond to light; does not reply to questions; has passed urine twice; unable to drink or unwilling; fed with a spoon.

Monday, August 29th. Had tranquil night; refused food; died this A. M. at 9.40 without a struggle.

An autopsy was made twenty-four hours after death by Dr. Cutler.

*Lungs.* Right entirely adherent from old inflammation. Left adherent at apex. Dependent parts of both lungs posteriorly congested. Bronchi healthy. Right lung more injected than left. A gland softened from old inflammation was found just outside of bronchus.

*Heart* atrophied; color good; consistence normal. Valves healthy with exception of a vegetation, not large enough to give rise to symptoms, on one of the curtains of the aortic.

*Spleen* four by three and one half inches; capsule moderately tense; color good; consistence normal.

*Peritonitis* old and limited on right and left sides of abdomen, also in pelvis.

*Kidneys* not abnormal.

*Liver* simply atrophied.

*Intestines* not abnormal.

*Left* slightly atheromatous.

*Left supra-renal body* was not disorganized; altered in shape from the well-known cocked hat to an irregular, lobulated appearance, the largest lobule size of a Lima bean. On section yellowish gray, homogeneous surface, with caseation, here and there softening; the size of organ but slightly increased.

*Right supra-renal body* presented the same appearances, only more marked; the largest lobule at top of gland size of end of thumb.

## PSEUDO-MEMBRANOUS LARYNGITIS COMPLICATING TYPHOID FEVER AND CAUSING DEATH.<sup>1</sup>

BY E. W. CUSHING, M. D.

WITH PRELIMINARY HISTORY OF THE CASE BY W. B. C. FIFIELD, M. D.

ON February 12, 1880, I was called in consultation by Dr. W. C. B. Fifield, to see a case of œdema of the larynx, as was supposed, of the previous history of which he has kindly written the following account.

"The patient, aged eighteen years, was seen for the first time on February 2, 1880. She had been complaining of fatigue and lassitude, accompanied with obscure abdominal pains for a week previous. The following points were then noticed, namely, tenderness on pressure over abdominal region, moderate distention, gurgling in the right iliac fossa; pulse 110; morning temperature 103° F.; evening 104° F.; slight diarrhœa; February 3d, two or three loose stools during the night; pulse 112; morning temperature 103° F.; evening 104° F. Still some tenderness of abdomen; tendency to diarrhœa. February 4th, pulse 112; temperature, morning 104° F.; evening 102° F.; diarrhœa. February 5th, morning temperature 103° F.; evening 104° F.; pulse 120; diarrhœa. February 6th, morning temperature 103° F.; evening 104° F.; diarrhœa; pulse 120. February 7th, temperature, morning 104° F.; evening 104° F.; pulse 120 per minute. This day rose spots were first noticed on chest and abdomen; diarrhœa. February 8th, Sunday, morning temperature 104° F.; pulse 130. Same condition of bowels, for which lead and opium pills were ordered. Evening, Dr. Stedman saw the case on account of my being too ill to visit her. Temperature 103° F.; pulse 130. Diagnosis of typhoid fever confirmed. February 9th, morning temperature 103.4° F.; pulse 120; less diarrhœa. February 10th, seen again with Dr. Stedman; pulse 120; morning temperature 105° F.; evening temperature 102° F.; pulse 110. Rose spots abundant; no diarrhœa. Complaints of roof of mouth being sore. Nothing to be seen either by Dr. Stedman or self. February 11th, morning temperature 104° F.; at one o'clock had fallen to 102° F. Still complains of roof of mouth. Nothing to be seen. Snoring respiration as if from nasal obstruction. Expectoration of purulent fluid. February 12th, morning temperature 104° F.; pulse 140. Difficult snoring respiration; cheeks purple; labored breathing. Seeing the impending suffocation I thrust my finger into the pharynx and immediately felt the

epiglottis, erect, stiff, and much swollen on the right; the swelling very hard; the whole rim of the glottis also seemed invaded by hard œdema. No membrane or deposit had ever been seen in the pharynx or upon the tonsils. A profuse discharge of muco-purulent matter followed the withdrawal of the finger with partial relief to the patient. Believing that I was in the presence of that very rare complication of typhoid fever, œdema laryngea, I telegraphed Dr. Cushing to come at his earliest convenience and to act independently, as my presence was required at the hospital for a tracheotomy there. At noon, Dr. Cushing not having arrived, I declined to do tracheotomy, on the ground that the young lady would probably not survive the operation, the pulse having risen to 160 per minute, and the labor of respiration not being sufficiently severe to momentarily threaten life. That I did not attempt it I deem fortunate, for at the post mortem the thyroid gland was found to so completely cover the trachea that one must either have cut directly through its substance or have levered it up with the handle of the knife; in either way I think there would have been bleeding enough to have put out the flickering life long before the operation had been completed. Alexander Tweedie, in his Lectures on Fevers, when speaking of œdema laryngea as a complication of typhoid says: "I have proposed tracheotomy in these cases, but never found any surgeon bold enough to perform it under so hazardous circumstances." Yet I imagine that Dr. Tweedie's cases were not parallel with mine. Somebody has spoken of laryngotomy as applicable. I cannot think that it would have advantaged in my case. Dr. Cushing will relate the appearances as he saw them, both in the living and in the dead body. I will only add that death took place very quietly at 9.30 o'clock the evening of February 12th, and that after the funeral on Sunday, the 15th, an older sister, who had been in the house during the last few days, came to me with well marked diphtheritic membranes on both tonsils. (Query. Does the thyroid gland become enlarged in typhoid?)"

On arrival I found the patient very weak, but perfectly sensible, and able to bear a laryngoscopic examination, which was made as she lay in bed by reflecting a clear north light which was increased by a field of snow. No spots were visible in the fauces or on the palate; the epiglottis was distorted to the right, much swollen, very red, and in such a position as to cover the glottis and obstruct the view.

The upper part of the larynx was also red and swollen, looking hard and firm, and clearly it was not a case of simple œdema. There was no membrane anywhere visible, and no record of the expulsion of any. The sputa when examined seemed simply muco-purulent, and although there was an account of paroxysms of dyspnea succeeded by the expulsion of a large amount of secretion, I had no suspicion of the real nature of the case. There was some dyspnea, but no sign of laryngeal obstruction, and therefore no indication for operative interference, even if it had not been contraindicated by the great prostration.

I expressed the opinion that the case might probably be one of perichondritis of the larynx, although a certain diagnosis was impossible. The young lady died the same evening of exhaustion, not of suffocation from any laryngeal obstruction.

At the autopsy there were unmistakable evidences of typhoid fever. The small intestine was studded

<sup>1</sup> Read before the Section for Clinical Medicine and Pathology of the Suffolk District Medical Society, April 8, 1882.

with infiltrated Peyerian glands and solitary follicles, while near the ileocecal valve were a number of ulcerations. Drs. Fifield and E. C. Stedman, who were present at the autopsy, agreed with me that there was no doubt but that the lesions were those of typhoid fever.

There were signs of hypostatic congestion in the lower lobes of the lungs, and some four ounces of dark fluid in the left pleural cavity.

The larynx was removed entire, with a piece of the trachea taken from just above the bifurcation.

When fresh the redness and swelling of the epiglottis and entrance of the larynx was marked, but we were surprised to find a distinct membrane lining the whole larynx and trachea, and extending into the secondary bronchi.

The bronchi and trachea were filled with masses similar to those expectorated and now seen to consist largely of broken down membranes.

The mucous membranes were not ulcerated, except at a small point on the anterior surface of the posterior wall of the larynx. The membranes were not firmly adherent, and were easily removed without leaving ulcerations under them.

There was no sign of perichondritis, or abscess, or necrosis of cartilage.

Such cases must be very rare, and it is difficult to say with certainty what the real nature of this one was.

Was it an accidental coincidence of diphtheria and typhoid?

Was it typhoid complicated by a croupous exudation on the air passages?

Is there any laryngeal and tracheal croup without diphtheria? The case opens up a burning question.

"*Wer darf das Kind beim rechten Namen nennen?*"

Most authors have little or nothing to say about such cases, and several physicians of large experience informed me that they never saw or heard of a case like this.

Many authors speak of necrosis and ulceration of the larynx (*diphtheritische Entzündung-Verschörfung-Verschörfung*) in typhoid, and Griesinger in *Infektionskrankheiten* (p. 169) mentions these, and also, (p. 191) after mentioning the violent catarrhal angina which extends to the air passages, says: "This often goes on to a patchy, pseudo-membranous coating (*Anflug*) and in places to an erosion of the mucous membrane." This process, or even the simple dryness, cause difficult deglutition and some pain in the pharynx. Such difficulties of swallowing may however arise from mere weakness of the muscles; in other cases they depend on disease of the larynx. Only in severe cases of anomalous course occur true croupous and diphtheritic processes in the pharynx, which sometimes spread in a ward by contagion.

"In such cases gray, firmly adherent, pseudo-membranes are found on the red and swollen mucous membrane, and these spread quickly over all parts of the pharynx, and often extend into the air-passages. There are then severe difficulties in swallowing, regurgitation, and in the latter case, aphonia, croupy cough, paroxysms of dyspnea, and generally a considerable increase of the fever and great prostration. This severe complication always occurs at the end of the first or in the second period (of the course of the disease), it is especially common when epidemic diphtheritis is prevalent (as at Paris,<sup>1</sup> 1851), and is usually fatal, more fre-

quently with symptoms of exhaustion than of severe local functional trouble.

"The immense collections of thrush (*Spor-pilzen*) in the mouth, pharynx, and oesophagus which were formerly usually considered as croup are similarly accompanied by a prostration which is generally serious."

Also on page 210 Griesinger says: "In the larynx and trachea there are developed in very rare cases, which are always very severe, simple croupous processes. In these cases the exudation usually begins in the pharynx, spreads over the epiglottis on to the respiratory mucous membrane to a variable distance, sometimes even into the finer bronchial ramifications.

Such processes occur occasionally, at the height of great epidemics, even in the very beginning of the disease, and are then accompanied by croupous exudation on other mucous membranes, especially that of the intestine, which, however, is accompanied by very slight typhus infiltration in the ileum, as appears to be the case also in primitive pneumo-typhus.

The croupous processes may, however, occur later, complicating fully developed ileo-typhus in the third or fourth week, or even after the commencement of convalescence, although nothing definite can be said about their causes. They are of great malignity, but, happily, very rare; they run a rapid course, usually fatal, with violent symptoms and speedy prostration. In the matter of diagnosis, besides the difficulty of breathing, the severe cough, the whispering voice, the lividity of the face, especial attention must be paid to the presence of pharyngeal croup and of coagula and bits of membrane (*Gerinnseln und Flocken*) in the sputa.

In the article on the Larynx, written by Eug. and Jules Boeckel for the *Nouveau Dictionnaire de Médecine et de Chirurgie Pratique*, no mention is made of diphtheritic inflammation of the larynx except as a form of ulceration, using the word in a German sense, not as implying a membranous covering. In other diseases, however, as scarlatina, variola, measles, the membranous laryngitis is described at length.

Under Diphtheria they say: "Secondary diphtheria always assumes the infectious form; this explains its gravity. The onset is generally insidious, and the local symptoms much less marked. If there comes on in a patient suffering from *typhoid fever* a diphtheritic angina the patient will not complain of his throat, and the affection will not be recognized except by direct examination. What usually marks the onset of the secondary diphtheria is a slight aggravation of the fever; it is, however, not marked, and not of long duration." . . .

In severe typhoid fever one can easily let an attack of diphtheria of the throat arise and run its course without suspecting its existence; the patient does not complain of it; he is not even troubled by it. If an enlargement of the submaxillary glands does not attract attention the intercurrent affection may be recognized only at the autopsy.

"Dans la *scarlatine*, la laryngite catarrhale est excessivement rare; elle revêt presque toujours d'emblée la caractéristique diphthérique, et présente alors une gravité qui varie d'épidémie à l'autre. Dans la *variola*, la laryngite se présente, sous une forme particulière, elle emprunte ses caractères anatomiques à l'ensemble de la maladie et constitue plutôt une *éruption pustuleuse laryngée* qu'une laryngite proprement dite. . .

<sup>1</sup> Conf. Culmont, *Revue Médecine-chirurgie*, de Paris, July, 1855.

Il arrive souvent en temps d'épidémie, qu'on observe à la suite de la variole des laryngites diphthériques, qui présentent un caractère de malignité tout particulière. *Laryngite morbillense.* La forme éréthémateuse peut passer à la forme diphthérique après une période de calme de quelques jours comme le prouvent deux observations de Coigne."

In Ziemssen's Cyclopaedia, under Typhoid (i. page 165), it is stated: "Under some circumstances diffuse diphtheritic and croupous processes may extend into the larynx, and there produce deeper ulcerations and disturbances. The mucous membrane of the trachea is, however, rarely invaded."

Von Ziemssen says laryngeal catarrh is a frequent complication of typhus and typhoid fevers. In the latter it is not uncommonly followed by more or less deep ulcerations, and by perichondritis with laryngeal oedema. He does not speak of membranes.

Steiner speaks of secondary croup in measles, scarlatina, small-pox, whooping-cough, epithelioma laryngis, *typhoid fever*, pneumonia, and cholera, but he gives no cases.

Sostier just mentions three cases of pseudo-membranous laryngitis in typhoid.<sup>1</sup>

Türk in his rich collection of clinical cases has recorded one similar to this. Under the heading Secondary Croup, he says: This frequently occurs in the course, or among the sequela, of exanthematic processes of typhus, of cholera, of typhoid, of pyæmia, and in fact often combined with other exudative diseases, for instance, pneumonia, pleuritis, pericarditis, meningitis. In secondary croup the membranes are frequently thinner than in primary, so that they often only appear as a membranous coating (Anflug) although thicker, more solid membranes do occur. Then follow clinical cases, among them one of croup in typhoid, as follows:—

"A baker's wife, apparently about thirty years old, was, according to the report of her physician, between the third and fourth week of an attack of typhus. Already in the course of the illness she had complained frequently of choking (Würgen) and collection of tenacious mucus in the fauces. These difficulties had increased for the last two or three days, during which the pulse rose simultaneously to 108. At the examination held by me on January 29, 1862, I found on the posterior and lateral walls of the pharynx, especially on the right, a white, thick, consistent, adherent, croup membrane, which extended also to the posterior surface of the soft palate, and so far forward that it bordered the edges of the arches of the palate and the uvula. The whole free border of the epiglottis and the right ary-epiglottic fold, in part, as well as the mucous membrane covering the right Wrisbergian and arytenoid cartilages, was covered with a similar membrane. The cords were normal. I have no information concerning the further course of the malady."

Türk apparently has not found this complication of typhoid so fatal as Griesinger would imply, for he says: "Larynx croup occurs both in exanthematic and in non-exanthematic typhus, in an early and in a late stadium, but it is almost always of inferior importance" (untergeordneter Bedeutung).

Mandl, regretting what he considers a useless division of the Germans of croup and diphtheria, according to the local symptoms, and declaring that we will not find pathology in tow of a globule, whose fantastic

voyages through meshes and pores defy the rich imagination of the poet, declares that "croup and diphtheria constitute a single great family, and croup is only diphtheria localized in the larynx; nevertheless pseudo-membranous affections of the larynx which are unconnected with diphtheria are also called croup. These are pseudo-membranous laryngitides which have neither the course, nor the reaction, nor the contagious specificity of diphtheria, and which cannot be considered as a stage of diphtheria not fully developed." Then he quotes Rokitsansky and the Germans as giving the name of secondary croup to these pseudo-membranous exudations in measles, scarlatina, typhoid, etc., etc., and says that their diphtheritic character is not yet proved.

He goes on to say, "The membranes are generally thinner than in diphtheria; they may occupy only the larynx, or this and its vicinity, taking their rise from some point of the pharyngo-laryngeal passages. They sometimes determine an acute and fatal oedema. I have noticed analogous exudations, grayish white, isolated, circumscribed, in syphilitic and tuberculous laryngitis and, as has been stated, in some cases of chronic parenchymatous laryngitis."

Further quotations would be tedious. The complication of typhoid fever by secondary croup, although rare, is well recognized, but not in the works in the hands of most general practitioners.

Published cases are hard to find, anatomical specimens must be very rare. I have therefore brought this case and specimen before you, hoping that it may not only be interesting in itself, but as a means of eliciting an expression of opinion concerning the real nature of such cases, which are connected directly with the question of the relation between, or identity of, croup and diphtheria.

## THE THERAPEUTICS OF VENESECTION.<sup>2</sup>

BY WM. A. DUNN, M. D.

It is difficult to recall a subject which so strikingly suggests the revolution which has taken place in therapeutics within the past quarter of a century, or which convinces an observer so earnestly that there is not that stability in the rules governing the application of medical means for ends which the practitioner would desire, or the symptoms of an illness demand. A practice which dates from the days of the father of medicine, and was so universally practiced in the ages following, winning for its adherents authorities like Galen, Sydenham, and Hunter, and in our day, Fordyce Barker, Graefe, Brown-Séquard, and Bowditch, could not have been so devoid of merit as the apathy and denunciation of these later times would seem to warrant. And yet if we reflect on the history of venesection we shall find that its course has not been much dissimilar from that of mercury, the alkaline treatment, and the various methods which have existed in our day, and which have won enthusiasts until time has tested their claims to merits, and placed them in their proper sphere. In their turn scoffers may deride the unlimited confidence we give carbolic acid, iodoform, and the salicylates, the abuse of which would operate as many evils as the abuse of venesection. Modern physiology and pathology have removed the ignorance which permitted the

<sup>1</sup> Traité de l'Angine Épidémique. Paris, 1852.

<sup>2</sup> Read at the meeting of the Section for Clinical Medicine and Pathology of the Suffolk District Medical Society, April 8, 1882.

many gross errors which prevailed in the days of wholesale venesection, a practice which was alike the function of the barber and leecher as well as the resource of the court physician. As we read of the many cases reported in which venesection was performed, apparently with the only aim in view to exhaust the patient as speedily and effectually as possible, we cannot help deploring the abuse of venesection, and wondering why the patient of a former generation was so difficult to be killed. The refinement of modern therapeutics as well as the barbaric precepts of the ancient bleeders have been the main factors which have brought venesection into disrepute. The advocates of blood-letting would seem to have cast odium upon their practices by the precepts which they taught. For instance, Dr. Elliotson, in speaking of enteritis, says: "The first thing one has to do is to bleed the patient well. You must set him upright as he can be, and bleed him from a large orifice without mercy." An authority no less distinguished than Robert Jackson, formerly surgeon-general of the British army, frequently removed four pounds at one time, which was considered a moderate bleeding. Six pounds have been taken on several occasions, and a hundred and twelve ounces at a single bleeding in some. This practice, so formidable in appearance, implied no danger. He declares the practice is reasonable in theory, and is proved by experience to be founded on truth. Certainly the results reported by Jackson were extraordinary, for he says that fainting did not always occur, and the patient in most cases returned to his military duty within eight days in the full vigor of health. Galen is quoted as having bled largely during the plague, and he is the first to record the quantity taken. He says that he has taken from the patient in one bleeding six pounds of blood, which immediately extinguished the fever, nor was there any loss of strength in consequence. In these days of pilocarpine, aconitine, atropine, and the subcutaneous syringe, we can reflect on the therapeutics of only a few years ago. If we are to credit the wonderful reports of cases of recovery after extraordinary losses of blood, we are warranted in relieving the popular mind of the terrors which it entertains concerning hemorrhages.

John Hunter is quoted as having seen several quarts of blood ejected from the stomach even by emaciated subjects, and improvement speedily followed the evacuation. Laevis relates the case of a man of seventy who suddenly lost in a threatened attack of apoplexy eleven pounds of blood from his nose, and four more in fifteen days afterwards, without any visible failure of strength. Boerhaave and Haller have both reported remarkable ha-morrhages which have not seemed to have been followed by any evil result.

Notwithstanding the many abuses to which venesection has been subjected, the fundamental principle presents claims for our attention and deserves application in special and well selected cases, and if we analyze the therapeutics of venesection we shall find sufficient cause for commendation and eager following.

There is no doubt that venesection was formerly used too indiscriminately and often employed too largely, but Dr. Flint says that with the natural tendency to pass from one extreme to the other it may be that the utility of blood-letting in certain cases at the present time is not sufficiently appreciated. The rules which governed the advocates of venesection in former times were in accordance with the lights which they possessed, and the methods which permitted the physi-

cian of a former time to continue his venesection until the coagulation ceased or until complete syncope declared itself, are a commentary on their limited knowledge of physiology and pathology. We now know without doubt that by a venesection we do not really diminish the amount of blood in the circulation, but we devitalize the blood of its most important factors, by robbing it of much of its fibrin and red globules, which are not readily reproduced. In accordance with fixed laws of endosmosis the blood becomes thinner and decidedly anæmic by its absorption of the fluids from other parts of the body, and in this manner the vital functions are impaired. It will be likely to effect harm, therefore, whenever it is important to economize the powers of life, and it may contribute to a fatal result in diseases which involve danger to life by asthenia.

Flint says that blood-letting is never indicated by the fact that acute inflammation exists; it is a measure directed not to the disease *per se*, but to circumstances associated with the disease. It is admissible, if with the development of inflammation there exist high symptomatic fever, the pulse denoting augmented power of the heart's action, the patient being robust, and the disease not involving danger to life by asthenia. Venesection is admissible under the conditions just stated whenever the promptness with which its effects are obtained renders it desirable to adopt it in preference to other measures producing the same effect with more or less delay. If we are to be consistent, we should be guided by the motto, *Naturâ duce*, of our Society, and we should receive many a suggestion from the natural operations continually presented to us in the natural course of a disease. Every one is familiar with the relief which comes to headache by an epistaxis — to the congested uterus by a menstrual flow, or to dyspnea by a slight hæmoptysis. I have at present a patient who has received within a few hours immense relief to a severe bronchitis by the appearance of her menses, when the ordinary remedies seemed to have failed. It is a well known fact that the temperature declines to an appreciable extent after an epistaxis, which, in most cases, is disproportionate to the amount of blood lost. Wunderlich says that after a moderate venesection the temperature rises a few tenths and gradually returns to the normal after a day or two, and may even at a later period sink below the normal.

Frese<sup>1</sup> says immediately after a moderate bleeding a fall of temperature of about 1° C. or 1.8 F. ensued, but after a few hours the temperature began to rise, and generally exceeded the temperature before the bleeding. Wunderlich says that general blood-letting in suitable cases of disease and in a less degree local abstraction of blood have a similar effect, and it not seldom happens that the temperature, which just before was considerably elevated, becomes normal, or very nearly so, soon after. In most cases the temperature soon rises again to its previous height or even exceeds it. The temperature will remain reduced just in proportion to the actual improvement which has taken place in the patient's condition, at or after the bleeding, and the most decided influence on the course of the fever is brought about by a sufficiently copious blood-letting or a spontaneous hæmorrhage (as in epistaxis or in menstruation). Granting that there are special indications for blood-letting, it is important to know when and how we are to avail ourselves of this agent and when to cease. Generally, a condition

<sup>1</sup> Virchow's Archiv.

of plethora with inflammatory symptoms would indicate it, especially if there is a full, bounding pulse. In limiting the amount of blood to be drawn we should not be guided by the condition of the pulse alone so much as by the improvement in the general condition of the patient. We are justified in supposing that many of the reported cases are grossly exaggerated, but it is an undoubted fact that venesection was much abused before the methods of the cold-water pack and the febrifuge effects of quinine were thoroughly appreciated. I have had an opportunity of testing the efficacy of venesection under the following circumstances.

Several months ago a patient whom I had never treated before presented himself at my office complaining of a headache, which was bilateral and at times very intense. His digestion was in good condition; he was not losing an appreciable amount of strength, and he was able to attend to his work, but with less vigor than formerly. As he was a great smoker and a hard worker I attributed his symptoms to an excessive use of tobacco and hard work. I advised him to rest, to moderate his use of tobacco, and to take tonics. There was no vomiting nor œdema, nor were there any symptoms which would attract my attention to his kidneys if I might except a slight dimness of vision, which, considered in connection with his headache and slight debility, caused me to request him to allow me to examine the urine, which he neglected to do. His age was forty-two. As he was an ordinary office patient he passed from my attention until late one evening I was called to attend him by a messenger who told me that the patient was suddenly seized with convulsions. I learned that the patient had continued to complain of his head and of amaurosis, but apart from those symptoms he had been apparently well until a few days before the convulsions appeared, and in fact he had continued working, although he was growing more feeble, and other symptoms which evidently indicated nephritis had supervened, such as œdema of the feet, hands, and face, with vomiting, and pain in the lumbar region, together with a diminution in the amount of urine passed. When I arrived at his house I found the patient in a profound coma, with convulsions. His pupils were dilated. His skin was dry and hot, and the frontal veins and face were moderately although not remarkably swollen. The œdema was slight. There was a full, bounding pulse, and the apex beat was abnormally labored, full, bounding, and slow. The temperature was 102° F., and the small quantity of urine which I was able to obtain was quickly coagulated by heat during the necessary delay prior to the application of the measures for relief, and relief was demanded at once. There was no time for the application of diaphoretics, diuretics, nor other derivatives. Death was imminent, and I believe would have speedily followed had not immediate action been taken.

I remembered that when I was a student in the office of Dr. H. I. Bowditch he had advocated venesection under proper conditions, and although I could not remember that I had heard any direct teaching given on the subject, I determined to bleed in the present case, and to follow the advice given by Dr. B. W. Richardson, and quoted by Dr. Bowditch, who claimed for venesection a first place in the treatment of uramic convulsions. I allowed ten ounces of blood to flow from the median cephalic vein, from which the blood came in a dark and steady stream. The relief which appeared after the venesection was not long delayed, and was most satisfactory. The convulsions ceased, the

face assumed a more natural hue, the pulse lost its labored character, the breathing became easier, and consciousness after a short interval returned. He was then wrapped in hot and moist blankets, and was given an eighth of a grain of elaterium. Perspiration was excited, and he rested easily. Under diuretics and jaborandi and milk at first, and afterwards Bashau's mixture, the patient made a slow and gradual recovery, with a single intermission on the fourth day, when it was necessary to remove five ounces of blood.

The urine at first contained abundant epithelial and granular casts; it was of low specific gravity, 1008, and contained a large quantity of albumen. After three months the albumen and casts had wholly disappeared from the urine, the œdema had disappeared, and, except a diminution of general vigor, the patient was really well.

I consider the case one of acute nephritis occasioned by exposure to cold in a patient considerably debilitated by hard work and general disregard of hygienic laws. Nephritis sometimes approaches so insidiously, and with symptoms so slightly emphasized, that a diagnosis is oftentimes difficult unless an examination of the urine is made. In this connection it may not be irrelevant to the subject to state that as obscure renal diseases are sometimes suspected by the single symptom of vomiting, to which Dr. Ellis attracted attention, so in like manner a headache, especially if bilateral, intense, and accompanied by amaurosis, may attract attention to a nephritis of which it may be at first the only symptom of dangerous conditions. The cry of venesection may be imagined to be, "Save me from my friends."

From the consideration of this subject we are justified in drawing the following conclusions:—

(1.) That although the errors of former days, without doubt, allowed a very great abuse of venesection, it has sufficient merit as a therapeutic agent to demand our earnest consideration.

(2.) If we are sincere in following the motto of our Society, *Naturā duce*, we shall take the suggestions which nature gives and bleed in carefully selected cases.

(3.) That in febrile attacks a loss of blood will lower the temperature, and this decrease in temperature is known to be disproportionate to the amount of blood lost.

(4.) That by venesection we do not actually diminish the volume of blood, but we cause the blood to become more watery, the free passage of the blood through the pulmonary circuit seems to be promoted, and the functional labor which the lungs have to perform is diminished by the abstraction of a certain number of the more solid particles.

(5.) It is fallacious to depend upon the condition of the pulse alone as the criterion of the amount of blood to be removed, or the benefit which the patient derives by a venesection. After a venesection the pulse sometimes appears to indicate increased power of the heart's action. The artery seems to strike against the finger with more force than before the abstraction of blood. Formerly practitioners were misled by this effect upon the pulse, and blood-letting was employed as a means of increasing the power of the heart's action. The sensation which the finger receives is delusive, and is caused by the quickness of the movements of the artery. This has been shown by the sphygmograph to depend on the diminished tension of the arteries following the abstraction of blood. It is to be borne in mind, says Flint, in estimating the power of the heart's ac-

tion by the sensible characters of the pulse, that the sense of resistance which is felt and the amount of pressure required to impress the artery are the evidences of strength. I cannot do better than to make use of the statements quoted in Dr. Bowditch's monograph on venesection which he read at the annual meeting of the Massachusetts Medical Society, in 1871.

"Dr. Richardson says: 'If blood letting were in this day an unknown remedy, and were some man to discover it, we should receive that man as the greatest amongst us, and send him to posterity as one of the lights of the age.' And again he says: 'The confidence of the ancients in the practice of blood-letting, their fearlessness of any immediate danger from it, was, I believe, as well founded in truth, as the cowardice and assertion, without observation, of the present day is founded on error.' He sums up as follows: 'I would recall that blood-letting as a point of scientific practice is still open to us in some stages (early stages) of typhoid fever, in cases where there is a sudden tension of blood, of which sunstroke is an example; in cases of chronic congestion of the brain; in cases of acute pain from (inflamed) serous membrane; in some cases of spasmodic pain (gall-stones, etc.); in others of sudden arrest of circulation from concussion; in congestion of the right heart, and it may be in some cases of extreme hæmorrhage. Above all I claim for it a first place in the treatment of simple uræmic poisoning.'

"Dr. Sutton<sup>2</sup> gives cases in which bleeding was resorted to to relieve distention of heart and passive congestion of the lungs. He ordered it, not to relieve inflammation, but to cure obstructions.

"Fordyce Barker, M. D.:<sup>3</sup> 'I am gradually getting to bleed more frequently. My conviction that this resource in practice has been too much neglected by myself and others has been progressively growing for some years.' Dr. Barker would bleed to prevent abortion in some cases.<sup>4</sup> So in renal congestions of the brain with coma, and when the skin is hot there is nothing so sure. He would bleed a woman in convulsions thirty ounces, and give claterium also. 'We must not,' he also declares, 'avoid bleeding in some cases even if the patient is feeble. In puerperal mania, at least in some very rare cases, venesection is of the greatest benefit.

## REPORT ON GENERAL PHYSIOLOGY.

BY CHARLES SEDGWICK MINOT, M. D.

AMONG recent investigations we select especially several important researches upon the nervous system and the function of respiration.

Professor Goltz, of Strassburg, has published a fourth paper<sup>5</sup> on the functions of the cerebrum, and has also gathered his memoirs on this subject into a volume that appears as a separate publication.<sup>6</sup> The numer-

ous experiments, which have been made during the last few years, on the localization of the functions in the brain by attempts to find specific centres in the *cortex cerebri*, seem to have accomplished little more than to show that electrical irritation of a limited area produces in each case a definite result, but it has not been proven that the constancy of the result extends always beyond one individual. On the contrary, one observer recognizes in a certain spot the centre for one action which another places elsewhere, while a third assigns to the spot another function. Until, therefore, the observers are agreed as to the functions and positions of the centres, the theory of circumscribed centres in the cortex cannot be definitely adopted.

Goltz's experiments put an even greater difficulty in the way of this theory. He has removed large portions of the brain in dogs by various methods, and has succeeded in keeping the animals alive for long periods after the operations were performed on them. He has found that the operation causes certain temporary disturbances, but that the permanent effect is a general diminution of the mental power, roughly proportional to the amount of brain substances removed. The extirpation of a circumscribed area never produces any definite, limited, permanent disturbance.

In his earlier experiments a canula was pushed into the substance of the brain, and a stream of water forced through it, thus washing off the nervous substance, but injuring the blood-vessels so little that there was no great bleeding. In the later experiments he used a bunch of fine needles soldered on to a plate (fourteen to a square centimetre), which he plunged into the part to be destroyed. Finally he used a White's dental engine to cut off pieces of the cortex. He divides the cerebrum into four quadrants by considering each half to be separated into an anterior and a posterior quadrant. The first dog, whose condition Goltz describes, underwent four operations at considerable intervals; each time nearly the whole of a quadrant was removed, yet the animal lived perfectly healthy for a year and eleven days after the last operation. It was then intentionally killed, and the brain showed not only the loss of substance actually removed, but had also undergone a very considerable atrophy. Now, this dog was extremely dull, stupid, and indifferent (*blödsinnig*), but still accomplished his cerebral functions, although imperfectly. He could see well enough to get assistance from his eyes in avoiding objects. When his eyelids were closed by sticking plaster he tried very awkwardly to remove the plaster, and when he moved bumped constantly against objects which he avoided with open eyes. He paid no apparent attention to anything around. Gave no heed to strange cats or dogs. He was not deaf, because he could be aroused from sleep by loud calls. He preserved his other senses likewise with greatly diminished acuteness. He was unable to manage his body in a way well adapted to the end in his view. Many ingenious and often amusing devices were employed to test his mental capacity. He might be characterized most briefly as a dull idiot, never making any expression of pleasure, although he could be put into a violent rage. Such were the permanent results of the injuries; the temporary effects were not less remarkable. After the first operation (removal of the left anterior quadrant) the characteristic disturbances appeared. When the dog attempted to walk the right legs yielded, and he

fell over. The spine was bent towards the left. Both eyes showed a tendency to turn towards the left. He did not perceive meat held before his right eye, which he recognized very well with his left. The sensibility of the skin was greatly depressed on the right side. He let his right paw be put in any position, etc., etc. *These phenomena nearly all disappeared within three months.* The surprisingly rapid reestablishment of the lost functions, thus demonstrated, is explained by the advocates of the localization theory by the supposition that the function of the destroyed centres is after a while assumed by the remaining centres. Each author assigns the new centres to a different position. Many a one boldly let "brain centres regrow like lizard's tails." After the last operation the dog had to be fed, but after several weeks he ate again alone. "The destroyed eating centre had grown again!" According to Goltz, the restoration of lost functions does not depend on new-formed centres, but on such as were already present, only with their activity inhibited.

A second dog lost both the posterior quadrants, and was kept in good health for several months. The whole of Munk's *Schspähre* (sight centre) was wanting. The animal was moderately dull (*in mässigen Grade blödsinnig*); he ate skillfully, moved about readily, had a subdued sexual instinct, saw quite well with both eyes, recognized no one, often ran to the wrong person when called, had little choice in selecting his food, etc.

A third dog lost both the anterior quadrants. His general intelligence and higher senses were less impaired than in the previous case; his tactile sensibility, on the other hand, was more diminished.

A fourth dog was deprived of both the left quadrants. Hardly any permanent effects could be noticed. His intelligence seemed fully preserved, his disposition unaltered, and his control over his body was very slightly, if at all, interfered with.

Without entering into further details, suffice it to say that, roughly speaking, the greater the amount of the cortex removed, the greater the diminution of the acuteness of the intelligence and of the senses. The operated dogs retained control over all the muscles of their bodies. No centre for any group of muscles was therefore wanting, nor was the use of any sense organ lost, but the stimuli produced a diminished effect. There is no evidence of any centres of temperament nor of any of the passions. The sexual instinct is lost in the same measure as the intelligence. None of the most important functions of the cerebrum can be assigned to circumscribed areas of the hemispheres. We can only say that the anterior quadrants have a more intimate relation with the movements of the body, and the sensibility of the skin. It is impossible, by any limited injury of the cortex, permanently to paralyze any muscle or even withdraw it from the influence of the will. Goltz adds several criticisms upon the views of the defenders of localization. Munk<sup>1</sup> has been especially unjust towards Goltz. The latter's reply uses very moderate language, but is effective.

Heidenhain and Bubnoff<sup>2</sup> have made an important discovery concerning the processes of irritation and inhibition in the brain. Heidenhain was led to this research by his studies on hypnotism. Since Fritsch

and Hitzig showed that electrical irritation of limited areas of the *cortex cerebri* called forth movements in definite corresponding groups of muscles, numerous experiments on these phenomena have been made. Herman<sup>3</sup> controverted the view deduced from these investigations that these results were due to the irritability of the gray substance, and emphasized the fact that similar motor effects could be produced by the irritation of the white fibres after the removal of the gray matter from the surface. The electrical currents might reach these fibres by spreading through the brain substance. If, however, it should be shown that it takes longer to produce the action in the muscle, if the cortex is irritated, than when the white substance is irritated, that would be an argument to show that the cortex is irritable, because in the latter case a certain time would be required to propagate the irritation; in the former case the same amount of time would be needed plus the time requisite to excite the cortex. François-Franck and Pitres<sup>4</sup> have shown that at least under the conditions of their experiments this difference exists. Their observations are in favor of the irritability of the cortex.

Heidenhain and Bubnoff chose the centre for the fore-leg, the position of which had already been determined. The muscle whose contraction they followed was the extensor digitorum communis longus. We cannot enter here into the details of the experiments by which the moment of irritation of the brain, and the moment of beginning, as well as the duration of the contraction in the muscle, was recorded with precision. The period from the influx of the irritation to the commencement of the muscular contraction is termed the reaction time. Our authors' first effort was to determine this time, and to analyze the causes which influence its duration. In the course of this investigation they were led to the important discovery to which we referred above.

They obtained the following results. The length of the reaction time varies within certain limits inversely as the irritation. When the strength of the irritation increases, the height of the contraction of the muscle increases, but the reaction time diminishes. This was overlooked by Franck and Pitres. There may be a summation of the irritations, which occurs the more readily the shorter the interval between them. The gray matter is directly irritable; the contraction does not depend on *Spronschleifen* striking the deep lying, white substance. In the gray matter the irritation arises (longer reaction time) and falls (slower fading out of the contraction) more slowly than in the white matter. The experiments were made on dogs dosed with morphia, the effects of which are not always sure, since in some cases the irritability of the animal is exaggerated and the reaction time greatly abbreviated; in other cases the reaction is excessively delayed. Their researches prove, the authors think, that the elements of the cortex are directly irritable. In further demonstration of this view they advance the observation that the epileptic attacks, which are sometimes caused by the cortical irritations, are produced by the action of the cortex; the subcortical motor apparatus can be set in epileptical irritation only by the action of the cortex. (For the demonstration of this see B. & H. pp. 170-174).

Entirely outside the range of previous experiences are the observations on the influence exerted by very slight tactile stimulation of the skin upon the irritability of the motor centres. If in that stage of morphia narcosis in which the animal is in deep sleep, but the irritability is not extinguished, the cortex is stimulated by a shock just too feeble to produce an effect (sub-minimal irritation), there occurs no muscular contraction; but a powerful contraction may be called forth if there is a gentle tactile excitation of certain parts of the skin just before the central shock is given. But the opposite effect, an inhibition of an active excitation, can be produced. Under certain circumstances the muscle makes a contraction and remains shortened for some time (*Contractur* of Tiegel). A gentle sensory impulse from the skin of the paw while the muscle is in the state of "*contracture*" immediately terminates the excitation and the muscle lengthens out. A similar irritation produces in one case an increase, in the other a diminution of the motor impulses. Various other gentle sensory excitations have the same inhibitory effect. The paradoxical experiment was made of producing a *contracture* of the extensor by reflex action from a strong pressure on the paw, and destroying it by a gentle tactile irritation of the skin of the paw. The question now arises whether instead of the sensory impulse a weak electrical irritation of the cortex would not produce the same result. Experiments gave an affirmative answer. If a *contracture* is produced either by reflex action or by a strong direct electrical irritation of the cortex, it can be ended immediately by a weak irritation of the same or any other spot of the *cortex cerebri*. Sometimes several successive weak irritations were necessary to produce complete obliteration. We thus learn that inhibition may result from a positive irritation, a discovery of the utmost importance, which reveals unsuspected complications in the central processes of innervation. Every irritation produces conditions which cause it quickly to end as soon as the stimulus ceases. Every irritation must be conceived to be accompanied by an opposite inhibitory process in the central organs. The effects of a stimulus may increase one or the other process, and in each case that process is most favored which is least developed at the moment of stimulation. A weak irritation during a period of rest favors a positive action, the development of efferent power; during activity it favors the development of inhibitory processes. It no longer remains necessary to assume the existence of distinct inhibitory centres. After a dose of morphia the energy of all the central activities sinks, but the inhibitory more rapidly than the excitatory processes, — hence the muscular actions assume a tonic character. In falling asleep, naturally similar changes occur; various little twitching movements occur, which in the waking state are inhibited. The imaginations are very vivid, because the inner excitations gain in duration and intensity from the suppression of the inhibition, until deep sleep puts an end to all activities. So likewise in the hypnotic condition a diminution of the inhibitory power causes an excessive effect to result from a stimulus, whether sensory or inner. If sensory excitations are induced in a hypnotic by arousing certain ideas or feelings, they become unduly powerful and lasting; there is a hallucination. Excessive hypnotic action in the brain (mind) or body may be terminated by a sudden draught of air upon the skin, just as the *contracture* could be brought to an end by a slight sensory irritation.

We have thus seen that inhibition is produced by a positive irritation, and that the same stimulus may cause excitation or inhibition according as it occurs respectively in a period of repose or activity in the excitation of the central organs. This important discovery has been verified by Luchsinger's<sup>1</sup> observations on snakes. He made the following experiment: Dehead an adder just below the level of the medulla, and suspend the body by a thread tied loosely around the neck. Presently the body begins to make a snake-like bend, which increasing in curvature lasts for about a minute, when the body suddenly drops and hangs limp. In about three minutes the movement begins again. These phases of contraction and rest continue rhythmically. A strong pressure during the period of repose causes the contraction to begin. A gentle touch upon any part of the skin during the movement causes it immediately to cease. Luchsinger points out that this experiment confirms Heidenhain's theory, but cannot be reconciled with Munk's<sup>2</sup> hypothesis of inhibitory action, namely, that it is not due to the relief of the central excitation, but to the action of antagonistic muscles, which mechanically counteract those already in contraction. Munk has also endeavored to help out his views by accounting for some of Bubnoff and Heidenhain's results through the assumption of exhaustion of the central organs by the second inhibitory excitation. To Munk's criticisms Heidenhain has made an effective reply.<sup>3</sup> In this essay, page 550, he shows that the difference between the strong excitatory and the weak inhibitory irritation is not due to the spreading of the currents to different depths in the two cases, because the contraction may be caused by a continuous irritation and inhibited by a brief irritation of the same strength, — in both cases the spreading of the electric current must have extended through the same parts of the cortex. This confirms the idea that we must attribute to the same central elements the functions both of excitation and inhibition.

The discovery that the condition of the parts at the time when the stimulus is conveyed to them affects the result produced by the stimulus opens the field to a very extensive series of investigations. This new line of research is begun by Wedenski,<sup>4</sup> whose experiments on the irritation of the vagus were made in Heidenhain's laboratory at Breslau. The latter points out in his last cited article the general bearing of Wedenski's work: especially that the same elements may be the instruments of both excitation and inhibition.

Wedenski experimented on rabbits. Both *vagi* were cut. The central end of the nerve of the right side was irritated by the induction current, either by a single closing and opening shock or by a brief tetanic irritation. The results by the two methods differed quantitatively only. *First*, irritation by a single (double) shock at the beginning of inspiration. The weakest current, that is effective, diminishes the depth of the inspiration just commencing and of the next following; the expirations are unaltered. A passing tetanic stim-

ulation produces a similar result, but the after effect is prolonged; with stronger irritations the effects are intensified and involve a diminution of expiration also. *Second*, irritation at the beginning of expiration. The minimum current that will produce an effect is stronger than in the case of inspiratory stimulation. The first effect is diminution of the expiration, with which is connected always a diminution of the next inspiration. This is natural, since the effect on the inspiration begins, as just said, with a weaker current. In the production of these effects it makes no difference whether the irritation is given above or below the *ramus largus recurrens*. The same irritation, according to the phase of the respiration in which it is induced, can favor or lessen the inspiratory powers. The lessening is shown by the diminution of the depth of the inspiration; the favoring is shown by the slowing and diminution of the expiration, which may be even converted into an inspiration. It will thus be seen that the irritation in each case tends to bring out that action, which at the moment of irritation is least developed: the same conclusion as was drawn from Bubnoff and Heidenhain's researches on the brain.

Continued tetanic irritation of the central vagus stem produces the following effects: (1.) Diminution of the depth of the inspiration without alteration of the frequency of the breathing; (2.) Diminution of the inspiration and expiration, with or without alteration of the frequency; (3.) Cessation of the breathing in either the inspiratory or expiratory phase. These results are closely analogous to the effects of brief irritations, in that with a weak current only the inspiration, with stronger currents the expiration also is impeded. Here, also, irritation during inspiration retards the same; during expiration favors the inspiration. For further details, especially as to the cessation of the respiration, we refer to the original.

The attempt to explain inhibition solely through the antagonism of muscles was made by Schliöser<sup>1</sup> and Munk, but has already many antagonists. In fact the theory does not hold water. There are many phenomena it cannot explain; thus the inhibitory action of the pneumogastric on the heart cannot be accounted for by antagonism, as there are no antagonistic muscles. Moreover, Rossbach<sup>2</sup> has shown that with the heart also a positive irritation during the systole produces inhibition — a mechanical irritation of the contracting frog's heart causes a local dilatation of the fibres of the region struck. It appears to be unaware of the relation of his observations to those of Heidenhain and others on the nervous system. Atropin destroys the inhibitory power of the vagus and the mechanical irritations over the systole. The beating of the heart continues, with normal diastole — hence we must regard the diastolic expansion as different from the inhibitory dilatation, since the former remains and the latter disappears in atropin poisoning. The diastole is to be considered as merely the cessation of the active contraction, — the inhibition as a positive active condition. Rossbach calls this a "*bis jetzt nicht gekannter Zustand*," a thing before undreamed of. But the general conception of inhibition here involved was advanced many years ago by Wundt,<sup>3</sup> and seems now definitely estab-

lished by several investigations, as this report is intended to show. It seems probable that the contractions and dilatations of the vessels follow the same general laws as the heart, — but future experiments will have to decide this.

Wegele<sup>4</sup> has shown that the Munk-Schliöser antagonism theory is not sufficient to explain the reflex inhibition of respiration after irritation of the trigeminus. The article contains a number of useful references to the older theories of inhibition. The experiments were made under Gad's supervision and upon rabbits. The respiratory movements were recorded graphically upon moving paper either by Gad's "*Aeroplethysmograph*" or by an elastic air bag pushed into the œsophagus (Rosenthal's method). If, when the breathing is quiet and normal, the nose is irritated, for instance, by ammonia, the result is a standstill in expiration, as Schill and others have reported. Now, if Munk's theory is correct, the prevention of inspirations is due to the excitation of the expiratory muscles, and therefore if the reflex centre of these muscle is severed from all connection with the trigeminus, then the irritation of the latter must no longer produce expiratory standstill. This separation was actually effected by cutting through the spinal cord at the level of the lower cervical vertebra; the expiratory centre lies below this, the trigeminus of course above. Irritation of the trigeminal nerve by ammonia still produced an expiratory standstill. The effect is therefore due to a direct inhibition of the inspiration. Other experiments of similar character gave a like result. In section four of his paper Wegele compiles various observations we may make on ourselves, all of which confirm the idea that inhibition is an active process, which may result from positive irritation. This conclusion must now be adopted, since it is the consequence of a considerable number of independent experiments by several authors. It is an important induction, and opens a very extended series of investigations.

Rosenthal<sup>5</sup> has published a useful summary of our present knowledge of the mechanism of respiration. He discusses particularly whether the cause of the movements is reflex action or, as Rosenthal has before maintained, the stimulation of the respiratory centre in the medulla by the blood. We call attention to this essay because it is a convenient and useful review, but, as it is not the result of a new original research, we give no abstract of it.

Aubert<sup>6</sup> has investigated the excretion of carbonic acid by frogs in an atmosphere containing no oxygen, having been led thereto by Pfliiger's experiments. Aubert found that, in ordinary air, from 1.5° to 27° C. the amount of CO<sub>2</sub> given off increases, though not in constant proportion to the temperature, as Moleschott and Hugo Schulz also found in their experiments. Aubert determined experimentally that the irregularity in the amount of CO<sub>2</sub> depends on the quantity of movement the animal makes. Air was deprived of its oxygen and introduced into a receiver of mercury. The frog was then passed through the mercury into the glass and allowed to remain for a long time, the whole

apparatus being kept at a given temperature. The animal was then withdrawn, and the carbonic acid left in the receiver determined quantitatively. *The excretion was just as great in the atmosphere without as in that with oxygen.* The fact that there was no ventilation of the receiver, but a gradual accumulation of  $\text{CO}_2$  in the air chamber, and the fact that the amount rises with the temperature,—the experiment lasting usually four hours,—show that we have to do not merely with the excretion of  $\text{CO}_2$  ready formed, but with actual production of carbonic acid. In other words, *the production of carbonic acid in the living organism proceeds independently of the absorption of oxygen.* Constant was the establishment of complete motionlessness in the frog after a certain time in air without oxygen, though the heart continues to beat. The time when this condition is established depends on the temperature: the frogs remain capable of motion at  $2^\circ \text{C}$ . for several days; at  $6^\circ$  to  $10^\circ \text{C}$ ., over five hours; at  $10^\circ$  to  $20^\circ \text{C}$ ., over two hours; at  $25^\circ \text{C}$ . and higher, only half an hour or less. There is an evident relation between the motility and the excretion of  $\text{CO}_2$ . Hence the general conclusion: The oxygen which enters in the combinations of the organism suffices for the maintenance of the decompositions necessary to keep up the animal function; the oxygen lasts for a time dependent on the temperature; likewise there is normally a definite stock of combinations present in the organism, which can be used to meet the expenditure of the animal functions. If this stock is exhausted there follows, in cold-blooded animals, apparent or false death (*Scheintod*). The heart keeps up its activity for a considerably longer period. A frog in "*Scheintod*" will recover in a few days if placed at first on ice. These interesting investigations teach us that between the absorption of oxygen and the formation of carbonic acid are many intermediate steps, and probably some of the intermediate compounds kept in store are broken up when the animal is placed in air without oxygen.

The theory of continual electric currents in muscle with all its complicated society of puzzling hypotheses, which was brought forward by Du Bois-Reymond, and has been for years so generally inculcated, seems now definitely set aside principally through Hermann's able investigations. The question has been actively discussed. Hermann's last article<sup>1</sup> is a reply to Du Bois' criticisms. The former seems to win by his arguments, and as he gives incidentally (page 488) the most concise presentation of his views we have met, we take advantage of the opportunity to offer a translation of Hermann's own summary: "The first fact which I have demonstrated, and others have confirmed, is that uninjured resting muscles and nerves are absolutely without (electrical) currents, and that to render them so neither cold nor other influences are requisite, as Herr du Bois-Reymond asserted. The second fact, or series of facts, is that the currents which appear in uninjured active muscles or nerves depend simply on the difference in time or in magnitude of the irritation at the points whence the currents are taken, and there are no currents when neither of these conditions is fulfilled. In proving these facts I had to correct errors and inaccurate statements of fact of Herr du Bois-Reymond. His statement was found to be incorrect

that the current during activity (*Actionsstrom*) of currentless muscles is situated on the supposed paraelectric ends of the fibres; incorrect his statement, etc." Hermann's theory is that when animal or vegetable protoplasm (or muscles or nerves) is altered at any point either by injury or by irritation, the altered spot becomes electrically negative with regard to the unaltered portions. There are no inherent currents in uninjured resting tissues, so that a great part of the cumbersome and perplexing fabric of "animal electricity" falls away.

## Reports of Societies.

### SUFFOLK DISTRICT MEDICAL SOCIETY.

#### SECTION FOR CLINICAL MEDICINE AND PATHOLOGY.

ALBERT N. BLODGETT, M. D., SECRETARY.

APRIL 8, 1882. Meeting called to order at eight p. m. The chairman, DR. GEORGE B. SHATTUCK, presiding.

A communication was received from the secretary of the Pathological Society of Philadelphia asking for an exchange of the Proceedings of the two Societies.

DR. HALL CURTIS then presented a paper on

A CASE OF ADDISON'S DISEASE, WITH AUTOPSY,

which is published at page 433 of the JOURNAL.

DR. FORDYCE BARKER, of New York, asked if Addison's disease were not a form of pernicious anaemia, and if the conditions observed in the supra-renal capsules might not be due to the phenomena attending pernicious anaemia.

DR. E. G. CUTLER, in answer to the question of Dr. Barker, said that the view of the identity of this disease with progressive pernicious anaemia was entertained and had been supported by good authority. In view of the striking differences in their clinical history, however, it seemed to him that there was an affinity rather than an identity of the two diseases. The pathology of the blood in Addison's disease had not been thoroughly studied. The enumeration of the corpuscles by Dr. Eies showed the existence of an anaemia not so profound as that usually seen in pernicious anaemia. Tubercle is frequently mentioned as a complication in these cases of Addison's disease, and in by far the greater number of the cases some disease of the lung is met with. Here, as is frequently the case, it was of some past time, and represented a cure. The changes frequently observed in the glands of the intestine were absent in this case, as was also any enlargement of the retroperitoneal glands. The caseous bronchial gland mentioned in the report of the autopsy was of interest. The clinical history would seem to direct attention to the nervous system and the blood in such cases, and these would seem to be the structures capable of explaining the changes observed in the tissues. The pigmentation of the ganglion cells described by some observers in this disease is not of sufficient rarity to give it great pathological importance, and the sclerosis of certain nervous filaments supplying the supra-renal bodies might well be a secondary phenomenon dependent on the primary change in the supra-renal capsule. The old peritonitis is of interest in view of the theories of some of the more recent observers.

DR. G. B. SHATTUCK referred to the paper by Dr.

<sup>1</sup> Hermann. Neue vermuthliche Argumente fur die Moleculartheorie des Muskel- und Nervenstroms. Pflüger's Arch., XXVI, 1851, 1852-1853.

E. H. Greenhow, by which the discussion of Addison's disease was preceded at the late International Medical Congress. Dr. Greenhow's researches had led him to the opinion, in which he was supported by Professor Semmola, of Naples, Dr. Guenau de Mussy, of Paris, and others taking part in the discussion, that morbid pressure upon or irritation of the abdominal nervous centres and terminations of the sympathetic, especially of the solar plexus and semi-lunar ganglion, the pneumogastric and phrenic nerves being thus indirectly affected, were most probably in many cases the proximate cause of the symptoms observed in this disease. In all the later cases examined by him, as well as by other observers, these conditions have been found. Dr. Greenhow cited a case of Professor Paget's of Cambridge, of lymphadenoma presenting the characteristic pigmentation and debility of Addison's disease. An autopsy showed that the semilunar ganglion and solar plexus were entirely involved in a mass of enlarged retroperitoneal glands lying in front of the spine; the supra-renal capsules were normal. The destruction of the supra-renal bodies by cancerous deposits and abscesses though unassociated with pigmentation, debility, and sub-normal temperature were cited on the one hand, and the pigmentation not uncommon in pregnancy and abdominal tuberculosis was mentioned on the other. Sir W. Gull had expressed the opinion during the discussion, in opposition to Dr. Greenhow, that probably all cases do not have a fatal course.

Dr. E. W. CUSHING read a paper entitled

PSEUDO-MEMBRANOUS LARYNGITIS COMPLICATING  
TYPHOID FEVER AND CAUSING DEATH.

which is published on page 435 of the JOURNAL.

Dr. Cushing asked, at the close of his paper, if it were probable that any disease may be complicated by diphtheria.

Dr. H. O. MARCY asked if the thyroid gland would have offered any obstruction to the performance of tracheotomy.

Dr. CUSHING replied that during life it was not detected, but at the autopsy was observed to be in a position to have greatly impeded the operation, and possibly to have terminated life from the consequent hæmorrhage in the feeble state of the patient during the latter hours of life.

Dr. SHATTUCK inquired the grounds upon which tracheotomy was deemed inadvisable.

Dr. CUSHING answered that the symptoms were too unfavorable, the pulse was small and thready, and there was fear that an immediate fatal result would attend the operation.

Dr. LYMAN asked the point in the history of the fever at which the laryngeal symptoms appeared.

Dr. CUSHING answered that the patient was taken sick on the 2d of February, and died on the 12th. On this last day the examination of the throat was made by the finger. There is no record of cough. On the 8th the throat was irritable. The patient had then been sick a week with the fever.

Dr. A. N. BLODGETT asked the condition of the mucous membrane in the throat at the time of the autopsy; if the false membrane adhered loosely to the surface of the mucous membrane, or if it was formed in its substance and implicated the tissues of the mucous membrane.

Dr. CUSHING replied that the false membrane was everywhere located upon the surface of the mucous

membrane, from which it could be easily lifted, and that the mucous membrane was everywhere perfectly normal beneath the exudation. There was no firm contact between the two; there was no ulceration or loss of substance in the mucous membrane.

Dr. W. A. DUNN read a paper entitled

THE THERAPEUTICS OF VENESECTION.

which is published on page 437 of the JOURNAL.

Dr. H. I. BOWDITCH was called upon for some remarks, and said that the paper contained many valuable suggestions for the present time. No doubt blood-letting was carried out in a heroic and irrational manner by our fathers, but that certainly was no reason why for twenty years past this useful procedure should have been virtually discarded from the practice of medicine. It is a fact that a great majority of the younger physicians of our day do not know how to perform a venesection. It is not taught among the other operations of minor surgery at Harvard University. If this total abandonment of what in certain severe acute cases is an important measure for combating disease is not a *reductio ad absurdum* it would be hard to define the term.

Many years ago, when in general practice, he found that abortion may be prevented by bleeding. In more than one case of threatened abortion the pains have been observed to cease, and in one instance, especially remembered, the hæmorrhage as well as the pains subsided after a moderate quantity of blood had been extracted from the arm. The loss of six or eight ounces of blood is scarcely noticeable in an adult. This is obvious from surgical operations and in labor. Bleeding should be employed in acute diseases of the brain, which are always or at least generally accompanied by congestion, though in these modern times we are told that there is no such condition possible as congestion of the brain. Often in delirium, with a hot and a flushed face, or in some cases of coma, bleeding is judicious treatment. In regard to the lungs, it is perhaps not wise to say that a pneumonia can be cut short, but doubtless some cases would be relieved of pain in the chest, dyspnoea, and in the end vastly benefited by the loss of a certain amount of blood by venesection. In pleurisy there was formerly no more common treatment than one or more bleedings. In our day nobody thinks of bleeding for a stitch in the side. Dr. Bowditch was conversing with a member of our Society, now unfortunately absent from illness, who advanced the idea that, if, in severe cases of pleuritic pains, with all the signs of acute pleurisy, we should bleed the patient when sitting up and until he felt a little faint, there would be fewer cases of large effusion and less tapping than we now have. This question was well worth consideration by practitioners. Dr. Bowditch was inclined to believe that there are a greater number of large effusions now than were found thirty or forty years ago. But whether if we bled whenever we met with a sharp pleuritic pain in acute cases, effusions would be less, he could not say, as he had no precise data on which to rest an opinion. But the question, he repeated, is worth the serious thought, not the supercilious contempt, of the profession.

In diseases of the heart bleeding is often of the greatest service. Even in chronic cases, when sudden dyspnoea comes on, congestion of the lungs, accompanied by rales throughout them, without effusion into the pleura, the results of venesection are often singu-

larly beneficial. In some cases it seems as if the heart were obstructed, and could no longer carry on the pulmonary circulation, and the withdrawal of blood is the means of prompt relief. One case of this character was thus treated, and fourteen ounces of blood removed, with the effect of complete relief of all actual distress, and the patient was comparatively well for a long time afterward. In some cases in which the pulse is hardly perceptible, and the heart, so to speak, swollen from the amount of blood contained in it, the relief from blood letting is very great. The pulse rises, and the heart's action becomes freer and easier, followed by great relief to the patient.<sup>1</sup>

Dr. FORDYCE BARKER, in response to a call from the chair, expressed his pleasure at being present, although he had not expected to take part in the discussion.

He said: Forty-two years ago I was a student of medicine in this city, with Drs. Bowditch, Shattuck, Perry, and Stedman as instructors. The room for study was 13 School Street, which had over the street door the sign "Lung Infirmary," and we had the opportunity of studying with our teachers auscultation and percussion on the patients who came in. I remember well that one chilly day in June a brick-layer came in his shirt sleeves, suffering from intense pain in his side; every breath was cut short by a groan. Dr. Bowditch examined him carefully with us, and finding no physical signs in his chest directed me to bleed him, and told me how to do it. With great anxiety I was successful in stabbing the vein, and a full stream of blood flowed. Very soon the man was perfectly relieved from pain, and Dr. Bowditch showed me how to close the vein. Our text-book on Practical Medicine was Marshall Hall, edited by the late Dr. Jacob Bigelow and Dr. Oliver Wendell Holmes, a book which I now often take down from my shelves with pleasure and profit, and I well remember my unexpressed surprise that Dr. Bowditch did not follow the rule of Marshall Hall, to bleed *ad deliquium*, but directed the vein to be closed as soon as the patient could breathe without pain. I went to see the patient the next morning, and found that he had gone to his work. This was my first lesson and experience in venesection. Although I have never given this up as a therapeutic resource, I believe that I have sometimes neglected it where I might have benefited my patient, but I do not think that I have ever carried the practice to excess.

Some ten or twelve years ago, on the afternoon of my landing from a steamer from Europe, I was called to see a patient in whom I thought venesection was indicated. As this was the first patient that I was

called to see I had no lancet in my pocket, and went to the only surgical instrument shop quite near to procure one, but found that there was none in the shop. It seemed to me an amusing illustration of the change of medical practice, that forty years ago every country store that sold sugar and tea and calico and clay pipes kept also lancets for sale, and that now in the centre of the population of a great city one would be compelled to go two miles and a half to buy one!

Soon after I wrote an essay on "Bloodletting as a Therapeutic Resource in Obstetrics," to which the author of the paper just read has referred. It is some years since I have looked at this paper, and I do not now intend to take up your time in recalling points which have already appeared in print. I do not remember that I have changed my views in any respect since that paper was published, but I think that I have had some additional confirmatory experience.

I understood the author of the very interesting paper to which we have just listened to express the opinion, and to quote Dr. Flint, whose authority carries the greatest weight with us all, that venesection should never be resorted to in asthenia.

It seems to me there are some important exceptions to this law.

I remember once being called suddenly to a lady who seemed to be dying from asphyxia. She was near the end of her first pregnancy, sitting in a chair, breathing with the greatest difficulty, or rather only making a great but unsuccessful effort to breathe, as I could hear no respiratory murmur. The action of the heart was labored and tumultuous, but the pulse at the wrist was hardly perceptible. Her emaciated face was livid and covered with large drops of perspiration. The danger of death was so imminent that I did not stop for further examination, but at once opened a vein in her arm. The pulmonary oedema and accumulation of the blood in the right cavities of the heart were due to the pressure of a gravid uterus greatly overdistended by an excess of liquor amni. Two days after she discharged an enormous quantity of this fluid, and was delivered, without much pain, of a dead hydrocephalic fetus. She recovered favorably, and has since had living children.

Some months since I was asked by a friend, a distinguished teacher of obstetrics, to see with him a primipara at about the seventh month of pregnancy, to consider the question of the propriety of inducing premature labor. She was suffering from excessive oedema of the trunk, the genitalia, and the lower extremities, and the urine was albuminous, coagulating almost solid.

She had no other grave symptoms. I recommended a variety of measures, particularly venesection, but opposed the induction of premature labor unless other symptoms should appear. But the case was a very important one, socially, and my friend had so much fear of pulmonary oedema that he brought on labor. The mother did well, but the child was lost. Six weeks after this, as often happens to us all, I was asked to see another case of precisely a similar character, and to consult as regards the same procedure. I should mention that in both cases incisions had been made in the labia, and in the latter case also in the legs, from which serum was drained in very considerable quantities. In the last case also vision was very much impaired, so that she could not read, although she could distinguish persons. This patient was first bled about twenty ounces. She was then given two drachms of

<sup>1</sup> Since the meeting Dr. Bowditch had, when called in consultation, advised venesection in the following case:—

It was that of a strong man, aged twenty-two years, who had been attacked six or seven days previously by all the rational and physical signs of double pneumonia: high fever, pain in chest, rusty sputa, dyspnoea, dullness on percussion, with bronchial respiration, bronchophony, and crackling rales in both backs, at lowest part. The pulse was quick, full, and strong. He naturally was considered as in a very hazardous condition, and on the question of venesection being raised, it was decided affirmatively. About twelve ounces were taken with great comfort to the patient. The oppression of breathing became much less, and the whole natural language of the patient was that of relief. It is true that about the same time the window of the room was opened, and the close, ill-ventilated atmosphere in which he had been lying for days was purified. This plan of having the window opened about an inch was continued afterwards day and night, care being taken by curtains, that the air should not fall directly on the patient, while the room was kept by a stove-heat sufficiently warm. Quinine and a tonic course was otherwise used. The disease was not cut short, but apparently the treatment moderated its severity, and helped towards the perfect cure which took place.

compound powder of jalap. After a free action of the hydragogue she was put on a rigid milk diet, and the tincture of the chloride of iron and digitalis. The œdema and all other unpleasant symptoms disappeared before labor came on. She had a living child, still alive, and her convalescence was only interrupted by a mild and short malarial attack.

Without taking up the time of the Society by an elaborate description of this point, I wish simply to express the belief, illustrated by the narratives that I have just given, that there are cases of extreme and dangerous serous plethora in the anæmic and the a-thenic which can be best and most effectively relieved by venesection.

I will mention a case of a different type from any referred to either by the author of the paper of the evening, or by Dr. Bowditch or myself.

Early in March I was called by a brother practitioner to see a lady forty-nine years of age, married thirty years. She had never been ill for a day since her marriage, except in 1854, when she had a rather severe attack of cholera. Her life had been a very happy one, having a devoted, loving husband, with abundant means to gratify every taste. She had no children, but had menstruated easily and regularly every month since her marriage. Some things that I learned led me to suspect that her sterility was not owing to any defect in her own system. She had menstruated early in August; September and October passed without any disturbing symptoms. Early in November she began to complain of insomnia, loss of appetite, wandering neuralgic pains, and for the first time in her life she became despondent, morose, and irritable. She lost a great deal of flesh, and became very taciturn, going on from bad to worse, until her appearance was that of a person in settled melancholia. Her physician, a man highly esteemed in the profession, was a classmate and old friend of her husband, and had always been like a brother with her, but for a few weeks she had not hesitated to show a great aversion to him. After a careful study of the case I proposed venesection, which was at first very coldly received by her physician; but it was soon apparent that the objection was mainly personal, as the doctor remarked that he had never bled any one. To our surprise, she expressed a warm approval of the proposal. As I opened a vein she watched the flow of blood with a most contented expression, and strenuously objected when I attempted to close the vein, after taking about sixteen ounces, and I therefore allowed four ounces more to flow. She then turned to her doctor and said, "If you had not been a fool, you would have done this weeks ago," and then, for the first time in many weeks, laughed heartily at her own remark. Her improvement from this time was in every respect wonderful. I was asked to see her again early in this month, and by her urgent request again took away about four ounces. It is sufficient for me to speak of the therapeutic results, and leave others to say whether we had to deal with cerebral congestion, subacute meningitis, or what the pathological condition was that was so happily removed by the venesection.

I will venture to relate another case in which I have felt a great interest, and which, it seems to me, brings out some other points bearing on this discussion, which, so far as I have seen, have not been brought out by writers on this topic.

In September, 1880, a lady from Massachusetts called on me with a letter from a Boston physician. She

was forty years of age, had been married twelve years. She had been delivered of one dead child, and had been subsequently pregnant seven times, and miscarried between the tenth and the eighteenth week with each, in spite of every precaution and of medical treatment to prevent such an accident. Her sentiment of maternity was very strong, and she was extremely anxious to have a living child, but she had very little hope. She was on a pleasure trip to West Point, Niagara, etc., but having passed one menstrual period she suspected herself to be again pregnant. On a careful examination I could not find the slightest evidence of disease in any pelvic organ to explain her repeated miscarriages. But the uterus was somewhat heavier than normal, low down in the pelvic cavity, and as she felt a necessity for much more frequent micturition than usual, I expressed the belief that she was about seven weeks pregnant.

She wished to return at once to her home if this was the fact. On inquiring I learned that always soon after pregnancy commenced her appetite became remarkably good, she gained rapidly in flesh, and between the eighth and tenth week she began to suffer from difficulty in breathing, palpitation of the heart, frequent attacks of vertigo, and sometimes severe but evanescent headache, which symptoms went on increasing until the fetus was thrown off. She took the greatest care of herself, seldom going out, but passing the most of her time on the sofa in her room. She was a woman of remarkable intelligence and kind feeling, and I explained to her my views in full. I told her that a healthy uterus in a healthy maternal system did not easily get rid of a healthy fetus until the proper time, that she seemed to have no disease of the organs connected with childbirth, and there was no reason from her statements to suspect that her abortions were the result of disease of the ovum. I therefore believed them to be due to a perverted condition of her general system resulting from pregnancy, and urged her to continue her pleasure trip, and during her pregnancy to take exercise and be out in the open air as much as possible. I recommended her to confine herself strictly to a milk and farinaceous diet, and two or three days previous to the time when menstruation would have occurred if she were not pregnant to be bled, the first time about sixteen ounces, decreasing the amount at each succeeding period. I wrote to my friend who had sent the patient to me, telling him what my advice to his patient had been, giving him as my theory of the case substantially the following opinion: Conception in this lady seems to stimulate very actively the nutritive and assimilative functions of the maternal system instead of those nervous activities which should nourish and develop the growth of the ovum.

My friend replied, in rather a derisive tone, with that want of respect of youth for their elders characteristic of the present age, that he "thought the theory creditable to my imagination and genius." He evidently had no faith in it, although he honestly began by carrying out the plan of treatment proposed. He first bled her, and I suspect she was the first patient whom he had ever bled, and that he performed this little operation with more trepidation than he usually feels in his great surgical operations in gynecology.

The patient was under the care of her family physician, a very able man in the city where she lived, and the plan of treatment suggested by me was faithfully carried out.

On the 14th of April, 1881, I received a letter in-

forming me of her happy accouchement with a boy still living. For a few days she appeared to do well; her physician frequently examined her urine, but found no albumen except a small trace a few days before her confinement. Three or four days after labor the urine became highly albuminous, the action of the heart feeble, and her general condition bad.

I visited her April 23d, and at that time, in addition to the symptoms I have mentioned, there were marked signs of threatening phlegmasia dolens. For a few days she apparently improved, but suddenly symptoms of heart failure came on again, and she died rather unexpectedly, I think, two weeks after confinement.

DR. BOWDITCH mentioned a case which he had recently seen in consultation in which venesection was advised, and the operation was attempted, but it was impossible to carry it out on account of the opposition of the patient, who was delirious. Leeches were applied with the effect of abstracting several ounces of blood; great improvement in all the serious symptoms observable in less than twenty-four hours.

DR. HARLOW observed that the case spoken of by Dr. Bowditch had occurred in his practice. The urine had been tested, and became solid from the amount of albumen it contained. The relief from the loss of this small amount of blood was surprising.

DR. BOWDITCH asked Dr. Barker the ultimate condition of the case last mentioned by him.

DR. BARKER replied that the patient died from uremic poisoning. Dr. Barker had maintained a frequent correspondence with the lady's physician in Boston, and had kept himself fully informed concerning the case. There had been no albuminuria until a few days before confinement. Within a few days after delivery albuminuria developed to an intense degree accompanied by phlebitis. Ten days after confinement the urine was rendered almost solid by nitric acid or heat; the heart's action was very feeble. The frequent bleeding was not thought to have induced the cardiac weakness, but to have been conservative in saving the heart's energy and prolonging life beyond what would have been possible without its aid.

Adjourned at 10.15 P. M.

## MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

### CALCIUM SULPHIDE AS AN ANTISUPPURATIVE.

DR. SMITH stated that reports of fifty-one cases in which the sulphide of calcium had been used had been received by the committee on restoratives, but before proceeding to a consideration of these he gave a short sketch of the history and properties of the drug, which had been prepared by Dr. John C. Peters. The first reports of cases were those made by Dr. W. T. Alexander, nineteen in number. In seven of these, however, the patients were not long enough under observation to afford any basis for a judgment on the effects of the remedy. In the twelve remaining cases the patients were treated for various periods ranging from five days to several weeks. Fifteen of the cases were of acne, two of furuncles, one of anthrax, and one of chancreoid with suppurating bubo. In most of the cases of acne, which were for the most part of the pustular variety, the results were very favorable.

<sup>1</sup> Concluded from page 421.

One case which was given with considerable detail was that of a patient suffering from papular and pustular acne, who came under treatment on the 11th of May. In accordance with Dr. Alexander's usual practice, a pill containing one fourth of a grain of sulphide of calcium was ordered four times a day. By the 26th there was some slight improvement, and the quantity was increased to five pills a day. By the 15th of June, however, it was found that the patient was worse than before, and the quantity was then increased to six pills. By the 28th of June there was very marked improvement, and on the 15th of July, the last date recorded, the improvement still continued. The case of anthrax was a very severe one, occurring in an Irishman. The carbuncle, which was as large as a man's fist, was situated on the top of the right shoulder, and was accompanied by moderate febrile movement. The treatment commenced on the 7th of June, the patient taking a pill containing one quarter of a grain of the sulphide four times a day, and by the 10th there was the most marked improvement, the pain having to a great extent disappeared, and the flow of pus entirely ceased. In regard to the use of the agent in acne, Dr. Alexander wrote that he employed it only in the pustular variety, and that in the papular form it was of no service.

Dr. Bayles, of Orange, New Jersey, wrote that he had used it in only two cases, but in both of them with the result of a speedy cure. The first case was one of suppurating bubo following non-indurated chancre, and the patient was quite well in a fortnight, in the meanwhile receiving no other treatment. The drug was given in the form of a trituration, containing one part of the sulphide to nine of sugar of milk, and the quantity of the former taken was half a grain three times a day. The second case was one of purulent ophthalmia, occurring in a strumous girl of eight years. Her general health had improved under the use of cod-liver oil, iron, and other tonics, but all means had failed to relieve the ophthalmia. It had lasted sixteen months without improvement when she began taking the sulphide of calcium, yet within ten days all suppuration had ceased. The dose was one eighth of a grain repeated every six hours, and it was given in a trituration of sugar of milk, as in the other case.

Dr. H. T. Hanks reported good results from its use in a number of cases of otorrhea, one of which was of twenty years' standing. It was given in quarter-grain pills every two, three, or four hours. In quinsy, and threatened quinsy in those subject to the affection, he had given it in four cases. In two of them the attack was completely aborted, while in one the course of the disease was apparently not at all affected. In the latter instance one grain was given, in pill, every two hours. In a case of suppurative endometritis the remedy, in the same doses, proved of no appreciable benefit. In another patient an attack of axillary abscess, to which she was subject, was entirely averted by the use of the sulphide. In three cases of threatened mammary abscess, however, it had no effect, and long and profuse suppuration followed. The conclusions which Dr. Robert Campbell arrived at after using the remedy in fifteen cases, the greater number of which were of acne, were, first, that it diminishes suppuration, and, second, that it at first improves the digestion, but after having been taken for some time tends to impair it. Dr. Flint had employed it in three cases of furuncles, and thought that the non-recurrence of the trouble

in any of them seemed to show its utility. Dr. V. P. Gibney reported its use in a case of bone disease with multiple abscess about the knee. For a considerable time the discharge was less profuse, and the ulcers seemed to be healing under the influence of the remedy, but a point was at length reached beyond which there seemed to be no further benefit. In another case an attack of recurring phlegmonous arthritis was recovered from in twelve days under the sulphide, given in one tenth grain doses every two hours. In a preceding attack, when syrup of the iodide of iron was employed, the patient recovered in a slightly longer period. Dr. Robert Amory, of Brookline, Mass., wrote that in two cases of furunculous pustules the remedy produced no benefit whatever. In one of them one tenth of a grain was given every two hours, and in the other one quarter of a grain was used three or four times a day, and the treatment maintained for a fortnight. In a third patient, however, an outbreak of multiple furuncles was immediately arrested by the sulphide. Dr. A. H. Smith reported a variety of cases treated by the remedy. The first was one of threatened abscess of the neck in a lady thirty-eight years of age. Iodide of lead ointment had been used without effect, and suppuration seemed imminent when the use of the sulphide was commenced, yet complete resolution ensued under its administration in doses of one eighth of a grain every two hours. In an infant sixteen months old a phlegmon of the neck, following pneumonia, was cured without suppuration, and in a case of hordeola the sty was promptly dissipated under its use. In a case of chronic abscess of the breast abscess of the axillary glands was averted by the sulphide, but in the case of a patient suffering from furuncles new boils continued to appear while he was taking the remedy. When the dose was doubled, however, the trouble entirely disappeared. Dr. E. C. Seguin wrote that he had used sulphide of calcium in doses of from half a grain to one grain, three to six times a day, in bromic acne occurring in cases of epilepsy, and that he believed its effect to be as good as that of arsenic. In two cases, indeed, it was even better. Dr. Brigham, of Burlington, Vt., wrote that he had employed it quite extensively in nearly all pustular diseases of the skin, and that he had obtained the best results in acute cases. The remedy was most successful in his hands in hordeola and small boils, but in a large carbuncle he had also obtained good results. Other cases were reported by Drs. G. H. Swazey and T. Hamilton Birch, of New York.

From this limited number of cases, Dr. Smith went on to say there seemed to be ample justification for the use of sulphide of calcium in suppurative affections, while at the same time there remained much to be learned in regard to the effects of the remedy and the position which it was entitled to hold among therapeutic agents. The fact that it was a drug which was more or less liable to irritate the stomach would seem to indicate the use of small doses repeated, and he thought that the best results could probably be obtained from it in doses of one tenth of a grain given every two hours. Even in small doses it sometimes caused headache, and in almost all cases it was apt to give rise to eructations of sulphureted hydrogen.

Dr. Smith's report now being open to discussion, Dr. WEBSTER remarked that since Dr. Sexton had read his paper before the Academy of Medicine, he had employed this agent in two cases of suppurative

disease of the ear with the most marked benefit, and then proceeded to relate them in detail. In the other cases in which he had resorted to its use, however, he had not seen any special effect from it.

Dr. SEXTON said he was glad to see that Dr. Webster was willing to acknowledge a good result from the use of the remedy in even two cases. Personally he had employed it for the past six or seven years, and he did not hesitate to say that the value of the drug was constantly increasing, in his eyes, as he became better and better acquainted with its effects. He had given it to infants only one or two months old; and in a child of three months which he had recently seen at the Eye and Ear Infirmary, suffering from a large subcutaneous abscess behind each ear, over the mastoid process, he had ordered from one fifteenth to one twentieth of a grain, in the form of a triturate, with sugar of milk, every two hours. The child was first seen on a Monday, and by the following Thursday the process of suppuration in one of the abscesses had been greatly hastened, so that he was enabled to make a free incision, while in the other the most prompt improvement had followed the use of the remedy, and its evacuation was uncalled for. Dr. Sexton also related other cases illustrating its good effects in ear disease and in quinsy, and then went on to say that he thought the drug had been unreasonably denounced by some. It was of great importance that it should be given with judgment, and that every case should be watched with the greatest care, so that the dose might be increased or diminished according to circumstances. In his experience better results had been obtained with it in subacute than in acute cases, and he had sometimes continued its use for several weeks consecutively.

Dr. PIFFARD remarked that there was always more or less uncertainty about any specimen of the drug, and that probably in no case was there pure calcium sulphide. If it was used in the form of *lepar's sulphur*, which was manufactured from oyster shells and brimstone, this was never free from impurities, while the sulphide of calcium itself would constantly become converted into the sulphate from exposure to air. A committee of the British Pharmacopoeia had investigated this subject, and ascertained that there was no pure sulphide of calcium, and hence they recommended the name *calcæ sulphurata*. The facts just mentioned, therefore, probably explained the reason for the failure of the drug in some, at least, of the cases in which it had been employed. Thus he had seen it given in two or three grain doses, and yet prove perfectly inert so far as any appreciable effect could be ascertained. In the latter part of the last century, Dr. Piffard continued, this remedy was much used as an antidote for mercury. Ten or twelve years ago Ringer recommended it in furuncles, and later Kane, of London, in acne. Dr. Sexton was the first to employ it in suppuration of the ear, and he believed that he himself was the first to resort to it in suppurative buho. He had used it in his venereal service at Charity Hospital, and had been surprised at the results which he obtained. Dr. Otis, whose term of service at the hospital succeeded his, had also obtained excellent results, which he had published. From his own observations he had no doubt that the remedy had a marked effect over acute suppurative processes. His experience with it in furuncles and acne had varied, but at the same time all the samples of the drug that he had used had

varied. Lately he had been experimenting with sulphide of potassium and hydro-sulphide of ammonium as substitutes for sulphide of calcium, as he suspected that in all such remedies it was the sulphur in an active, soluble form that was the efficient agent. As to the physiological effects of calcium sulphide, there was but little known beyond the account which Hahnemann had given of it, which was mixed up with other matter, and altogether unsatisfactory. Dr. Alexander had stated in his paper, however, that the drug gave rise to furuncles when administered to the healthy subject.

Dr. O. B. DOUGLAS said that he had treated two cases with the remedy. One was a case of submaxillary abscess, following scarlet fever, which had been treated without success by various methods for a week. Sulphide of calcium was given in the form of a triturate, and in three or four days the trouble was cured. The other case was one in which vaccination was followed by bad effects, pustules appearing in various parts of the body. In this instance, however, no benefit was obtained from the remedy. Dr. Douglas then read a letter of regret from Dr. Amory, of Brookline, Mass., who had expected to be present on this occasion. Dr. Amory also sent an interesting communication from Professor Jackson, of Harvard, in regard to the bad effects, in the form of suppurative disease, which were produced in a number of individuals by the leakage into his laboratory of carbonic disulphide in gaseous form.

### Recent Literature.

*The Sympathetic Diseases of the Eye.* By LUDWIG MAUTHNER, M. D., Royal Professor in the University of Vienna. Translated from the German by WARREN WEBSTER, M. D., Surgeon United States Army, and JAMES A. SPALDING, M. D., Member of the American Ophthalmological Society, etc. New York: Wm. Wood & Co. 1881.

The monograph before us is the first of a series in which the author proposes to embrace the whole domain of ophthalmology. Of the few already published it is, without doubt, the one possessing the most general interest, and we are glad to welcome it in an English dress. The affection discussed is one concerning which every physician may be called upon for advice, and outside of the larger cities it will not always be possible for him to refer the patient to a specialist, while the importance of a correct appreciation of the dangers involved, and of the prompt application of the remedy, cannot be estimated too highly.

It was the object of the author in these monographs to popularize, in the best sense of the word, the subjects of which he treats, and we know of no writer on ophthalmology to whom such a task could better have been intrusted. The book reads almost as flowingly as a novel, and this attraction is obtained without any sacrifice of clearness to effect, nor is its professedly popular character made an excuse for lack of thoroughness. The trained oculist, as well as the general practitioner, will be repaid for the time given to its careful perusal.

The work is, in our opinion, a very valuable one, and if the personal opinions of the author are now and again strongly emphasized, this can hardly be regarded as a defect in consideration of the fact that he does not

conceal that there is a difference of opinion on some points. The views on which we should be most disposed to take issue with him are those of the inherent benignity of sympathetic iritis serosa and the harmfulness of enucleation in the presence of that disease, but how simple the practice of medicine would be if all physicians held precisely the same views on all subjects.

The author regards both the optic and ciliary nerves, either alone or together, as paths for the transmission of the sympathetic affection, the optic nerves conveying irritative and inflammatory conditions from the optic nerve and retina, while inflammations of the uveal tract are carried by the ciliary nerves.

The idea now gaining adherents, that inflammation is propagated from one eye to the other through the lymph spaces of the optic nerve, with or without the mediation of microbia, is one which has found its advocates only since this monograph was written.

In general we have only commendation for the work of the translators, but we have noted a few slips; for instance, on pages 122 and 123, where the author is speaking of the form of inflammation which travels along a nerve discontinuously, skipping from one point to another at some distance, *discontinuirlich* is translated as "step by step," and *springweise* as "gradually." We shall hope to see these and like errors corrected in a second edition. Meanwhile we thank the translators for having placed the book before a wider circle of readers.

*Cyclopædia of the Practice of Medicine.* Edited by DR. H. VON ZIEGLER. Volume XX. General Index. New York: William Wood & Co. 1881. 499 pages.

The stores of knowledge contained in the original volumes are made readily accessible by this important addition. The usefulness of a single volume is greatly enhanced by a well-made index; by what proportion to the number of volumes the value of an index increases, it is not possible to state, but every owner of the Cyclopædia will certainly find that the twentieth volume adds very greatly to the value of the original nineteen. The volume bears evidence of great care in its compilation, and will prove a great economizer of time and labor.

—At the annual meeting of the Essex North District Medical Society, held at the Essex House, Lawrence, on Wednesday, May 3, 1882, the following officers were elected for the ensuing year: President, Dr. C. N. Chamberlin, Lawrence; Vice-President, S. K. Towle, Haverhill; Secretary and Treasurer, George W. Snow, Newburyport; Corresponding Secretary, E. P. Hurd, Newburyport; Commissioner on Trials, F. A. Howe, Newburyport; Nominating Councilor, C. G. Carleton, Lawrence; Councilors, Drs. H. J. Cushing, Merrimac, C. G. Carleton, Lawrence, O. D. Cheney, Haverhill, A. B. Dearborn, Newburyport, O. H. Johnson, Haverhill, M. Roberts, Lawrence, C. C. Talbot, Lawrence, O. Warren, West Newbury; Censors, Drs. John Crowell, Haverhill, F. B. Flanders, Lawrence, C. D. Hunking, Haverhill, R. C. Huse, Georgetown, J. F. Young, Newburyport.

# Medical and Surgical Journal.

THURSDAY, MAY 11, 1882.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year including postage.*

*All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.* HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

## EXPERT TESTIMONY IN CASES WHERE THERE IS A QUESTION OF INSANITY.

In a recent address before the New York Medical-Legal Society by Dr. E. C. Spitzka there are some excellent criticisms upon expert testimony in cases where there is a question of insanity, although we cannot entirely agree with the author as to the best remedy for the evils in the case. The difficulties to which attention is called are twofold: first due to the incompetence or want of truth and fairness on the part of the expert witness, and second from the readiness with which experts assume the position of medical counsel in defense of their side of the controversy. The evils are acknowledged, and many men could bring forward illustrations of the way in which justice is defeated as striking as any which might be cited by Dr. Spitzka, whose sharp condemnation of testimony in some of his allusions seem to us to arise from his having not fully got at the real meaning of the witnesses whom he criticizes.

In objecting to some of the extraordinary statements made on the witness-stand, Dr. Spitzka well says,—

"In epileptic insanity, sometimes comprising eight per cent. of asylum admissions, no morbid appearances can be found in a large number of recent cases, and those found, such as asymmetry of the brain and skull, indicate rather the frequent hereditary and congenital origin of the disease than explain the exact basis of the insanity. Even in advanced cases of epileptic insanity, it is not the exception to find but very slight and doubtful indications of the disease post mortem. With chronic mania, dementia, and other terminal deteriorations, the brain is more constantly diseased, it is diminished in weight, the convolutions appear shrunken, the cells of the brain-rind wasted, the blood-vessels show the vicious influence of long-continued disturbances of the blood supply, but even here there are cases where the post-mortem evidence is not conclusive. With imbecility and idiosyncrasy anatomical evidences of imperfect brain development are common: in a case of this kind the murderer, Redemeier, executed at St. Louis, a portion of whose brain I exhibited at a meeting of this body, evidences of an arrest of development as well as associated peculiarities of the skull were found. Finally, in progressive paresis of the insane, the disease familiar in some of its prominent features to those who attended the meeting devoted to a discussion of the Gossling case, the post-mortem record is more satisfactory. It is safe to say that if in a case

where this disease is claimed to have lasted longer than a year, certain changes in the nerve centres are not found, the opinion is seriously impaired.

"Summarizing the teachings of the master minds in pathology, of reliable observers generally, and my own experience, I consider myself justified in saying that positive and indisputable evidence of insanity cannot be found in more than thirty per cent. [?] of the insane, that in another thirty per cent. [?] slight changes are found, not differing in character, though perhaps in extent, from what we observe in some sane subjects, while in the remainder there is no visible deviation from the normal standard of any kind."

These facts ought to be so well known that it should hardly be worth while to call attention to them, but, unfortunately, they are frequently ignored. Dr. Spitzka's sole remedy for the ignorant expert's testimony weighing with the jury as strongly as that of the best informed lies wholly in the lawyer's right to cross-question to the last degree. But experience has shown again and again that the witnesses most ready in standing cross-examination are by no means always those whose evidence is most valuable, and the judge cannot often know enough of the matter of the evidence to be able to say, as one of our justices of the supreme court once said, that he knew the expert was lying. The remedy, so far as there is any, lies in the hands of the medical profession, so long as the lawyers do not wish any change, and the laws will not enforce any. Physicians can refuse to give *ex parte* testimony, and insist upon their right to answer every question fully and fairly, no matter whether in so doing they are injuring "their side" or not. Already Massachusetts has taken a long step in advance by the counsel for the government and the defense, in criminal cases, referring the question of insanity to a competent commission, and abiding by their decision, as is now not infrequently done.

## JAMES R. WOOD, M. D.

DR. JAMES R. WOOD, one of the most distinguished of American surgeons, died at his residence on Irving Place, New York, on the 4th of May, from an attack of double pneumonia, which lasted only four days. On Sunday, the 30th of April, while on the way to his country seat at Oyster Bay, Long Island, he was taken with a severe chill, and on his return to his town house in the evening was found to be very ill. Professors Austin Flint and Alonzo Clark were called in consultation, but the disease steadily progressed, and for twenty-four hours before his death he was in an unconscious state. The funeral services were held at All Souls' Unitarian Church, of which the late Dr. Bellows was pastor, on Sunday, the 11th, and were attended by representatives of all the medical societies of which he was a member, and an immense number of the profession at large.

Dr. Wood was born in the lower part of New York City, September 14, 1816, of Quaker parents, and received his preliminary education at the Friends' Seminary. He studied medicine with Dr. D. L. Rogers

and attended two courses of medical lectures, the first at the College of Physicians and Surgeons, New York, and the second at the medical college at Castleton, Vermont, where he received his degree of M. D., and where he was immediately afterwards appointed demonstrator of anatomy on account of the distinction that he had won in that department while an undergraduate. He commenced practice in New York in 1837, and was soon assigned to a position in the out-door department of Bellevue Hospital. From the first he exhibited the warmest possible interest in that institution, and through his agency constant reforms were made in its administration, and its efficiency and usefulness were constantly increased. In the cause of medical education he also found a most congenial field for the exercise of his talents and energies, and no student could help feeling the influence of his glowing enthusiasm. He was the first to introduce bedside teaching at Bellevue Hospital, early recognizing, as he did, the desirability of combining clinical with didactic instruction, and about the year 1850 he held his first regular clinic.

It was one of the desires of his life to see a great medical school established at Bellevue, where there was such an abundance of material for clinical study, and the first step towards this was the organization of what was known as the Pathological School, which he established in 1856 in a small building obtained from the Commissioners of Charities and Correction. Later he was one of the founders of the Bellevue Hospital Medical College, which grew out of the latter, and he was at once appointed professor of operative surgery and surgical pathology, a position which he retained till 1868, when he was elected emeritus professor of surgery. Up to the time of his death he maintained his weekly clinic on Saturday afternoons at Bellevue Hospital, which was probably the most popular ever held by any teacher in New York, and was always attended by from seven hundred to a thousand students and practitioners, while his offices were continually crowded with private pupils. In accordance with his general plan of providing as many facilities as possible for the intelligent study of medical and surgical science, he took a prominent part in securing the passage of the bill which provided that the bodies of unclaimed vagrants should be given to medical schools for dissection, and many years ago he began making the collection which is known as the Wood Museum of Bellevue Hospital, and which now contains four thousand specimens, many of which are very rare and some altogether unique. This museum was always his special pride, and at the hospital it is said that scarcely a day has passed for a generation in which he has not visited it, and added something to its value.

Of Dr. Wood's remarkable skill and attainments in operative surgery it is scarcely necessary to speak. He was the first to perform, in 1810, tenotomy of both masseter muscles for false ankylosis of the inferior maxilla, and his successful treatment of congenital deformities of the lower extremities by the aid of the knife early won him great distinction. His widest

renown, however, was achieved by his brilliant resections in various parts of the body, in which he met with unparalleled success in the preservation of the periosteum for the formation of new bone. His most famous case was that of a young girl suffering from phosphorous-necrosis of the jaw acquired by working in a match factory, in whom he removed the entire inferior maxilla. The periosteum was left intact, and as it retained its vitality, a new and complete jawbone was formed from it. The patient died some years afterwards, and her skull is to-day one of the most valuable specimens in the Wood Museum. It is related that when a photograph of this was sent to Berlin, Langenbech told his class that he did not believe that a skull corresponding to it existed; and Dr. Wood hearing of this at once sent the skull to Europe to convince him of the fact. A man in whom he performed the same operation with the same admirable result is still living. Dr. Wood tied the subclavian artery not less than five times, with success in each instance, and the external iliac in eight cases, only one of which he lost. He was equally successful in the ligation of the carotid, femoral, and other large arteries.

The Wood bi-sector, for the removal of stone, which he invented, was received with great favor both in Europe and America, and he himself used the instrument in more than one hundred successful operations. He was the author of numerous pamphlets on surgical subjects, and it is believed that he has left in manuscript for publication some more or less extended records on the subject of clinical surgery. He was a member of all the principal medical societies, and was twice elected president of the Pathological Society, of which he was one of the original founders in 1844. At the time of his death he was visiting or consulting surgeon to more than twenty hospitals and dispensaries.

Dr. Wood's decease is universally recognized as a very signal loss to the medical profession and to the city in which he spent his useful life, and the flags of the various medical colleges as well as of the St. Nicholas and other clubs have since been displayed at half-mast in token of respect for him. The career of such a man reflects the highest honor upon American surgery: while his character was such as to win the respect and affection of all who knew him, and his memory will long be honored by the whole country, as well as the community in which he was more especially known. Dr. Wood was married in 1853, and his wife and three children survive him. Of the latter the eldest daughter is the wife of a grandson of Valentine Mott.

— A very simple dropper may be made by bending a piece of glass tube at a right angle, and drawing one end out to a point. On inserting the other end into the bottle, and gently inclining the latter, some of the liquid will ascend along the tube, even before the liquid in the bottle has reached the mouth, and may be dropped at will.

## AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

SOME of our readers may be interested in the announcement of the thirty-first meeting of the Association, which is to be held at Montreal on the 23d of August, 1882, under the presidency of Principal Dawson of McGill University. Its sections on Biology, Histology and Microscopy, and Anthropology justify us in calling special attention of the medical profession to its coming meeting.

A large Local Committee has been formed and through its several sub-committees is actively engaged in perfecting the local arrangements for the meeting, which will soon be announced by special circular. It is only necessary to state here that the committee, of which T. Sterry Hunt is chairman, are desirous of doing everything in their power to promote the objects of the Association, and that their circular will contain information relating to the local arrangements, hotels, and the special rates of transportation, as well as the general programme for the week. The headquarters of the Association will be at McGill University.

Special invitations have been sent by the Local Committee to distinguished scientists abroad, and it is believed that several will be present.

The offices of the Local Committee and of the Permanent Secretary will be at the University. The General Sessions and the meetings of the Sections and Committees will also be held in the University buildings.

Members expecting to attend the meeting are particularly requested to notify the Local Secretaries, Messrs. S. C. Stevenson and Frank W. Hicks, at the earliest moment possible.

All members and Fellows must forward to the Permanent Secretary, as early as possible, and when practicable before the convening of the Association, full titles of all the papers which they propose to present during the meeting, with a statement of the time that each will occupy in delivery, and also such abstracts of their contents as will give a general idea of their nature; as no paper can be read in any Section or Subsection until it has been received from the Standing Committee and placed on the programme of the day by the Sectional Committee.

The receipt of a *Title of a Paper* simply is not sufficient to secure its being placed on the printed list of papers received, and it is particularly requested that the abstracts be prepared *ready for printing* in the volume of Proceedings. Blank forms for giving the titles and abstracts of papers will be furnished by the Permanent Secretary on application. The Standing Committee particularly request, in order to facilitate the arrangement of the programme, that the titles and abstracts should be forwarded so as to reach the Permanent Secretary *before August twentieth*.

At the last meeting of the Standing Committee it was determined to adopt the plan of *printing abstracts of all the papers read* before the Sections in the Proceedings, beginning with the Montreal meeting, unless by a special vote, on recommendation of a Sectional

Committee, it should be decided to print the paper by title only, or, in exceptional cases, in full.

The custom of placing upon its Standing Committee the names of its past Presidents is one which insures the wisest counsels in its management and which might be copied by other associations with profit.

## WHAT LUNATICS THINK CONCERNING THE RESPONSIBILITY OF THE INSANE.

AT the debating society in the Lunatic Hospital at Hanwell, England, there has been a discussion among the patients on the question of the responsibility of the insane for murder. The conclusion was strong and decided that the outside public was mad on the subject; that lunacy ought not to be a defense, because, as a rule, insanity is never so complete as to extinguish all perception of all sense of responsibility. To test this matter it was proposed to offer the insane criminal a red-hot poker, see whether he would grasp it, and upon the result of that ingenious experiment settle his responsibility, — an ordeal of fire less destructive than that of the Middle Ages. It must be said, however, that one of the men who shot at the Queen of England admitted that if his predecessor in the same crime had been executed rather than let off on the score of insanity, his own crime would not have been attempted.

## MEDICAL NOTES.

— The ninety-first annual convention of the Connecticut Medical Society will be held at New Haven May 24th and 25th.

— A new respirator, for use in impure air, has been introduced in Germany, the peculiarity in its construction being that separate air-passages are provided for inhalation and for exhalation. A light mask of gutta percha, covering the nose and neighboring parts, has before the point of the nose a prolongation containing wadding — pure, or saturated with some suitable substance — between two pieces of wire gauze, and having an aperture below, covered by a hard rubber valve which opens outward. The inspired air must pass through the wadding, while the expired air preferably passes out through the aperture, and thus no precipitation of the products of expiration takes place in the wadding.

— Professor E. S. Morse, of the Essex Institute, has devised an ingenious arrangement for utilizing the heat in the sun's rays in warming our houses. His invention consists of a surface of blackened slate under glass fixed to the sunny side or sides of a house, with vents in the walls so arranged that the cold air of a room is let out at the bottom of the slate and forced in again at the top by the ascending heated column between the slate and the glass. The out-door air can be admitted, also, if desirable. The thing is so simple and apparently self-evident that one only wonders that it has not always been in use. Its en-

tire practicalness is demonstrated in the heating of the professor's study in his cottage at Salem. The value of the improvement for daily warming buildings like churches and school-houses, which, when allowed to get cold between using, consume immense quantities of heat before they are fairly warmed again, is evident. Of course some other means of heating must be available when the sun does not shine. But in the colder regions, say in the far Northwest, the sun shines a greater part of the time, and hence the saving of artificial heat would be very large if the sun-heat could be "turned on" for eight or ten hours out of the twenty-four. — *Sanitary Engineer.*

— Dr. J. W. Collins, of Toronto, Ohio, states, in a recent number of the *New York Medical Record*, that he vaccinated X, of that place, in January, 1882; and that, although she had had a severe attack of confluent small-pox in 1873, she had all the symptoms of a perfect vaccination.

— "Doctor" Richard C. Flower, who paid a fine of \$200 in the Court of General Sessions of New York, recently, for practicing medicine without a license, has delivered a lecture in Boston on The Little Lords of Creation, or the Allopathic Czars.

## Miscellany.

### TENEMENT BLOCKS.

WE find the following on tenement blocks in the number of the *Lowell Bulletin* for April:—

Lowell has had boarding-houses of all kinds from its first settlement, but no tenement blocks, strictly, till within a few years. As such blocks in other cities have been found most prolific sources and causes of disease, it is the dictate of wisdom and prudence that their character be well understood, especially as the erection of these buildings seems on the increase in the city. It is singular that the first experience Lowell had in this direction was on so large a scale as "Little Canada" presents. It is thus described by an Agent of the State Board of Health and published in the Report for 1880: "Its area is less than two acres; its population, according to the census just taken, is 1,076 souls, who live in twenty-four tenement-houses. In addition to these, are one unfinished tenement-house, five stables, eight carriage and wood sheds, one bake house, and sixteen privies, or slop-hoppers, the two latter having 115 divisions. The one tenement-house yet unfinished, is, in construction, of the worst pattern, the ground-floor of one entire end of the building being occupied by privies, built into the house, and having sleeping-rooms overhead. The buildings are most of them three stories or less in height, and are so close together that it is difficult to pass between them. There are others (and with windows, too) so near on the side next to the neighboring building, that a person cannot pass between, where the eaves overlap, and the rooms are dark at three p. m. One of the newest buildings in Little Canada, a huge, three-story, flat-roofed caravansary, 206 by 41 feet, has a population of 336 persons. Every tenement in this building (four rooms usually, except the end ones) has two dark rooms, lighted by small, high windows into the kitchen only; and totally dark, unventilated rooms are not infrequent through the entire district."

The average cubic feet of air provided for the breathing of each occupant will not much exceed 200 feet, whereas the lowest estimate for good health is from 500 to 600 feet. When these tenements are fully occupied, it makes the densest population in the United States except a district in Ward Four, New York.

No fact in the history of sickness or reports of mortality is better established than that such tenements and districts are the hot-beds of disease, especially in summer. Infants die by the score with cholera infantum and bowel complaints. Should scarlet or typhoid fever or diphtheria break out in a malignant form, they would spread like a pestilence. Such tenements as the above cannot now be built in New York or Boston, as the law provides for ventilation, regulates the privies, requires a certain distance between tenements, and allows only a little more than half of the land to be covered with the building. It is unfortunate that Lowell has not such a law, as several tenement blocks are being built in the city.

### PROLONGED GESTATION.

IN the May number of the *New York Medical Journal and Obstetrical Review* Dr. Louis A. Rodenstein, of New York, reports four cases of prolonged gestation, and remarks that the number of cases cited upon undoubted authority by every writer on obstetrics, and the cases constantly reported as occurring under the personal observation of general practitioners, go to show that prolonged gestation is not a myth, and especially that it should not be explained away by questioning the virtue of the mother. How long the duration of the period of gestation can extend beyond the normal time is not yet determined, perhaps can not be determined, but that it may extend over two months is apparently settled. The same principle is involved, whether the uterus tolerates the presence of the child three days or one hundred and forty-five days (Professor Meigs's "Report") after the natural term of gestation has expired. He believes that, after the uterus has performed its physiological function of gestation for the natural term, it rests from the work of gestation proper. Why does it not, then, exercise the function of expulsion? That question he does not attempt to answer, but believes that after gestation has performed its proper and peculiar work the growth of the child is complete, and it thereafter lies dormant in the womb. Otherwise the child would grow to huge size, and its delivery in the natural way would be impossible; whereas in the cases cited the size of the child at the expiration of the period of prolonged gestation was normal.

### MONTHLY BULLETIN OF THE MORTALITY AND SANITARY CONDITION OF LOWELL.

THE Lowell Board of Health in proposing to issue a monthly bulletin, the first four numbers of which have come to hand, says,—

"The primary object of all boards of health is the prevention of disease. The modes of doing this are various. Among them the removal of filth, the building of sewers, the introduction of pure water, etc., are the most important. These agencies must be carried on by legislation and municipal authority. In this way

the causes of disease on a large scale are reached, and, to a certain extent, may be removed. But in order to support these agencies and carry them out in detail, information on the subject must be generally diffused among the people. In no other way can this knowledge be so well communicated as by boards of health. It is everywhere made the duty of these boards to report once a year or oftener to the public on health matters, giving the "vital statistics" and such advice as the public may seem to require. In many instances

these reports are largely made up of figures and tables, which may interest a few persons, but are not instructive to all classes. Both these objects are important, and should be secured as far as possible. We propose to issue, the coming year, a monthly bulletin, giving the mortality each month, together with such facts and comments as may exhibit the sanitary condition of the city. These bulletins will be printed in a form convenient for preservation, so that at the end of the year, when bound together, they will become valuable.

## REPORTED MORTALITY FOR THE WEEK ENDING APRIL 29, 1882.

| Cities.                            | Population by Census of 1880. | Reported Deaths in each. | Deaths under Five Years. | Percentage of Deaths from         |                |                       |                |            |
|------------------------------------|-------------------------------|--------------------------|--------------------------|-----------------------------------|----------------|-----------------------|----------------|------------|
|                                    |                               |                          |                          | The Principal "Zymotic" Diseases. | Lung Diseases. | Diphtheria and Croup. | Scarlet Fever. | Small-Pox. |
| New York.....                      | 1,206,590                     | 787                      | 334                      | 25.65                             | 17.92          | 6.86                  | 8.27           | .76        |
| Philadelphia.....                  | 846,984                       | 381                      | 110                      | 15.48                             | 10.23          | 4.19                  | 2.36           | .79        |
| Brooklyn.....                      | 566,689                       | 292                      | 126                      | 30.47                             | 15.75          | 12.33                 | 10.27          | —          |
| Chicago.....                       | 503,304                       | 219                      | 108                      | 31.51                             | 18.26          | 6.85                  | .46            | 5.94       |

Deaths reported 2864 (no reports from St. Louis and Cleveland): 1069 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 631, consumption 384, lung diseases 376, diphtheria and croup 170, scarlet fever 131, small-pox 85, typhoid fever 50, measles 45, diarrheal diseases 35, cerebro-spinal meningitis 29, whooping-cough 29, malarial fevers 22, puerperal fever 17, erysipelas 16, typhus fever one. From *typhoid fever*, Philadelphia 19, New York six, Chicago, Boston, and Cincinnati four each, Brooklyn and Baltimore three each, District of Columbia and Cambridge two each, Milwaukee, Holyoke, and Haverhill one each. From *measles*, New York 24, Chicago 11, Philadelphia six, Brooklyn and Pittsburgh two each. From *diarrheal diseases*, New York 15, Chicago seven, Boston five, Cincinnati and District of Columbia two each, Brooklyn, Baltimore, Pittsburgh, and Milwaukee one each. From *cerebro-spinal meningitis*, Chicago 10, Worcester three, New York, Philadelphia, and District of Columbia two each, Boston, Baltimore, Cincinnati, Pittsburgh, Milwaukee, New Haven, Charleston, Fall River, Fitchburg, and

Woburn one each. From *whooping-cough*, New York 12, Chicago four, Brooklyn and Charleston three each, Boston and Pittsburgh two each, Philadelphia, Cincinnati, and District of Columbia one each. From *malarial fevers*, New York 11, Brooklyn nine, Baltimore and Nashville one each. From *puerperal fever*, Brooklyn four, New York, Chicago, and Boston three each, Cincinnati, Pittsburgh, Milwaukee, and Quincy one each. From *erysipelas*, New York and Philadelphia three each, Boston and Cambridge two each, Brooklyn, Chicago, Baltimore, Pittsburgh, Providence, and Lynn one each. From *typhus fever*, New York one.

One hundred and nineteen cases of small-pox were reported in Cincinnati, Baltimore 24, Pittsburgh 15, Milwaukee seven, Holyoke five; diphtheria 11 cases, typhoid fever four, scarlet fever two in Boston; scarlet fever 17, and diphtheria three, in Milwaukee.

In 36 cities and towns of Massachusetts, with a population of 1,018,232 (population of the State 1,783,086), the total death-rate for the week was 22.27 against 21.36 and 22.26 for the preceding two weeks.

For the week ending April 8th, in 173 German cities and towns, with an estimated population of 8,398,933, the death-rate was 27.5. Deaths reported 4435; under five 2070; pulmonary consumption 714, acute diseases of the respiratory organs 483, diphtheria and croup 203, diarrheal diseases 138, scarlet fever 83, whooping-cough 77, typhoid fever 41, measles and rubella 33, puerperal fever 21, small-pox (Essen three, Benthien, Darmstadt, Königsberg, and Strassburg one each) seven, typhus fever two. The death-rates ranged from 17 in Mannheim to 48.2 in Nuremberg; Königsberg 27.3; Breslau 29.5; Munich 40.8; Dresden 28.4; Berlin 24.5; Leipzig 23; Hamburg 23.5; Hanover 25.1; Bremen 27.6; Cologne 28; Frankfurt a. M. 24.8.

In the 28 English towns, with an estimated population of 8,457,514, for the week ending April 15th, the death-rate was 24.4. Deaths reported 3956; acute diseases of the respiratory

organs (London) 392, whooping-cough 221, measles 162, scarlet fever 74, fever 58, diarrhoea 43, diphtheria, 35, small-pox (London eight) 13. The death-rates ranged from 16.9 in Derby to 34.6 in Sunderland; Sheffield 18.9; Birmingham 24.4; Bristol 25.6; London 23.1; Leeds 22.1; Liverpool 26.7; Manchester 34.5. In Edinburgh 21.3; Glasgow 27.5; Dublin 28.3.

For the week ending April 15th in the Swiss towns, population 494,390, there were 57 deaths from acute diseases of the respiratory organs, pulmonary consumption 41, diarrheal diseases 24, diphtheria and croup two, typhoid fever five, scarlet fever and whooping-cough two each, puerperal fever one. The death-rates were, at Geneva 19.6; Zurich 24.3; Basle 32.6; Berne 18.4.

The meteorological record for the week ending April 29th in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the U. S. Signal Corps:—

| Date.            | Barometer. | Thermometer. |          |          |            | Relative Humidity. |             |       |            | Direction of Wind. |             |            | Velocity of Wind. |             |            | State of Weather. <sup>1</sup> |             |                       | Rainfall.         |  |

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM APRIL 29, 1882, TO MAY 5, 1882.

WILLIAMS, JOHN W., major and surgeon. Granted leave of absence for six months. S. O. 101, A. G. O., May 2, 1882.

JAQUETT, G. P., major and surgeon. Granted leave of absence for six months on surgeon's certificate of disability. G. O. 97, A. G. O., April 27, 1882.

FOSTER, JOSEPH V., captain and assistant surgeon. The extension of his leave of absence granted him in S. O. 17, C. S., Military Division of the Atlantic, is further extended twenty days. S. O. 99, A. G. O., April 29, 1882.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.—A regular meeting of the Society will be held on Monday, May 15, 1882, at the hall, 19 Boylston Place, at eight o'clock, p. m. Reader, Dr. J. J. Putnam. Subject, Present Aspect of the Question of Cerebral Congestion. Action on proposed Amendment to By-Laws. C. M. JONES, Secretary.

BOOKS AND PAMPHLETS RECEIVED.—Monthly Bulletin of the Morbidity and Sanitary Condition of Lowell, Mass., for the Month of January, 1882.

The New England Family of Nathan Allen, M. D. (Reprinted from the New Englander for March, 1882.)

Twenty-eight Registration Report of Rhode Island.

Fermeuse Infant Food. By George B. Fowler, M. D., late Instructor in Physiology, College of Physicians and Surgeons, New York. (Reprint.)

Fifteenth Report of the Medical Staff of St. John's Hospital (Lowell, Mass.). Submitted at the Annual Meeting, April 3, 1882.

The Evidences of Insanity discoverable in the Brains of Criminals and others whose Mental State has been questioned; with some Remarks on Expert Testimony and the Grapapote Case. By Edward C. Spitzka, M. D., President of the New York Neu-

rological Society, etc. Read before the New York Medico-Legal Society, May 3, 1882.

The Case of Guiteau. A Psychological Study. By George M. Beard, M. D., New York. (Reprinted from the Journal of Nervous and Mental Diseases, Vol. IX, No. 1, January, 1882.)

Current Fallacies about Vaccination. A Letter to Dr. W. B. Carpenter, C. B., etc. By P. A. Taylor, M. P. Second edition of 100,000. London: E. W. Allen, 4 Ave Maria Lane, E. C. 1881.

Electricity in Surgery. By John Butler, M. D. New York and Philadelphia: Boericke & Taft.

Observations on Surgery in Children. By Edward Borek, M. D., St. Louis, Missouri. Read before the St. Louis Medical Society, April 1, 1882. (Reprint.)

Twenty-second Annual Report of the Superintendent of the State Asylum for Insane Criminals, Auburn, N. Y. For the Year ending September 30, 1881.

Atti della Reale Accademia di Medicina di Torino. Vol. VI. Fasc. 1. Sulla Struttura del Midollo Spinale per Dott. G. B. Laura. Torino, 1882. Tipografia Colaninzi & Comp.

Circulars of Information of the Bureau of Education. No. 1. 1882. The Inception, Organization, and Management of Training Schools for Nurses.

Hygiene in Relation to the Eye. By C. J. Lundy, M. D., Professor of Diseases of the Eye, Ear, and Throat in the Michigan College of Medicine. Detroit.

Gonorrheal Ophthalmia, its Complications and Results; Iridectomy for Artificial Pupil. A Clinical Lecture by C. J. Lundy, M. D.

A Contribution to the Study of the Bacterial Organisms commonly found upon the Exposed Mucous Surfaces and in the Alimentary Canal of Healthy Individuals. Illustrated by Photomicrographs. By George M. Sternberg, Surgeon U. S. Army. Experiments with Disinfectants. By George M. Sternberg, Surgeon U. S. Army.

Thirty-Sixth Annual Announcement of Starling Medical College, together with Catalogue and Order of College and Hospital Exercises for the Year 1882-83. Columbus, Ohio.

Bacillus Anthracis. By George M. Sternberg, Surgeon U. S. Army. With Plate. (Reprinted, with Additions, from the American Monthly Microscopical Journal, August, 1881.) New York: Thompson & Moreau, Printers. 1881.

## Lectures.

### CLINICAL LECTURE ON A CASE OF IDIOPATHIC ANÆMIA.

BY ROBERT T. EDES, M. D.

THE patient, John D., was questioned by a member of the class, and the following history obtained:—

He was twenty-five years of age, born in New York, living in Cambridge, where he was employed as a grocer. He had never had rheumatism, diphtheria, typhoid, or intermittent fever. His appetite, until the present illness, had been good, and his diet substantial and varied. He had considered himself a strong man, and was in the habit of lifting barrels of sugar into a wagon. There had been no hæmorrhage from lungs, stomach, bowels, or urinary organs, and but a very slight epistaxis on one occasion. No suggestion was made by him of any previous debilitating or depressing influence, physical or moral.

Some six weeks ago he first noticed a loss of color in his face. Appetite poor. For four weeks before entrance there had been dizziness and occasional headache, with noises in the ears. For two weeks pain in the chest and cough, without expectoration. The bowels were regular. There was nocturnal micturition once or twice. There were no nervous symptoms of consequence, except more or less "cramp in legs for three months."

On inspection the patient was seen to be a muscular young man, not emaciated, but exceedingly pale, his skin being almost yellow and the mucous membranes nearly white. He expressed himself as feeling strong, and was not sure that he could not at that time lift a barrel of sugar out of a wagon, although half an hour before he had nearly fainted in walking from the ward to the lecture-room.

Upon the surface of the thorax were seen a few dark-red purpuric spots, not much larger than a pin's head, and also a few bluish bruise-like spots, which he said were where "the doctors had pounded him." The legs were similarly but much more profusely marked with the red spots.

There was no sponginess of the gums, except at one very small point. Physical exploration of the thoracic organs revealed nothing abnormal except a soft systolic murmur, loudest along the left edge of the sternum. At the base of the neck on the left side a hum was heard with each sound of the heart, and on the right side a short systolic souffle.

The anterior border and part of the upper and lower edges of the spleen could be made out, showing it not to be enlarged. Nothing abnormal was detected in the abdomen. No enlarged glands were found anywhere.

A drop of blood drawn from the finger was evidently exceedingly pale and watery. A hasty microscopic examination showed that the red corpuscles were very scanty, but the white were not increased.

A more careful examination on the next day gave as an average of several counts, all less than 800,000, 670,000 red corpuscles to the cubic millimetre. (The normal is about 5,000,000.)

The corpuscles were not so much deformed as they are sometimes found, although some of them were very deeply cupped, a change which is probably the result simply of a swelling of the interior of the corpuscle

out of proportion to the envelope. They were not markedly larger than normal, but were not measured. The tailed and divided corpuscles which have been figured were not seen, nor was there any large proportion of microcytes.

There was nothing marked at this time about the pulse or temperature, nor, although the latter was not recorded from day to day, was there any indication of a febrile movement during the progress of the case. The urine had been examined and found to be pale, acid, of specific gravity 1014, containing no albumen, and no abnormal sediment.

A previous ophthalmoscopic examination had shown numerous retinal hæmorrhages in both eyes, chiefly situated near the outer edge of the disk, extending out into the neighboring retina, and arranged in a somewhat radiating manner, following the course of the vessels.

The treatment for the three days of his hospital residence had been tincture of the chloride of iron, with such food as he could take. The gentleman who examined the case considered it one of "progressive pernicious anæmia," for which the instructor proposed to substitute Dr. Addison's original name of "idiopathic anæmia," because although the first mentioned might represent correctly the usual course of the disease, and in this case a very probable prognosis, yet there are fortunately some cases presenting these symptoms which are not progressive or fatal.

It was remarked that this disease, although not difficult to distinguish, has quite intimate relationships with several interesting blood diseases.

From all forms of leucocythæmia it is at once distinctly separable by the absence of any excess of white corpuscles.

From two forms of pseudo-leucæmia, those connected respectively with enlarged spleen and enlarged lymphatic glands (Hodgkin's diseases), the normal condition of those organs easily distinguishes it, unless in cases where glands not accessible to inspection are the ones at fault.

A case was mentioned of a middle-aged man who, without obvious cause, became feverish and had night sweats. He lost appetite and flesh, and became anæmic (2,500,000). There was no excess of white corpuscles; microcytes not noted. After death the only lesion found was a great hypertrophy of the retroperitoneal glands, with a little suppuration at one point.

Dr. Pepper's theory, however, that idiopathic anæmia represents that form of pseudo-leucæmia connected with disease of the osseous marrow is not so easily disposed of, and it is to be accepted or rejected chiefly upon data to be obtained after death.

Scurvy is usually to be recognized by its origin under peculiar hygienic conditions, and by the sponginess of the gums.

The present case, however, bore a very strong resemblance to ordinary purpura, and in the absence of history might easily have been mistaken for it, as, indeed, it actually was for a day or two, owing to a lack of attention to the order in which the symptoms developed.

In the case before us there had been absolutely no hæmorrhages of any consequence. Those which have been mentioned were important only as symptoms, and could not all together have accounted for a fraction of the loss necessary to reduce the patient to his bloodless condition.

The altered condition of the blood was evidently the

cause and not the consequence of the hemorrhages. No positive symptoms, except the evident facts of extreme anæmia and the preservation of the adipose tissue, threw much light upon the diagnosis. The deformity of blood corpuscles was no more than has been found in other forms of anæmia. The retinal hemorrhages have, to be sure, been considered highly characteristic, but there seems no reason why they should not occur in any disease with a hemorrhagic tendency as well as in the present.

A condition of anæmia almost exactly resembling in external appearance that found in the case under discussion was to be noticed in a young man upon the other side of the ward, who had had a long-continued and profuse hæmaturia.

Singularly enough, however, this last patient, though almost as pale, both as to skin and mucous membrane, as the one before us, who had less than one million red corpuscles to the cubic millimetre, had a globular richness of over four million; a fact which certainly suggests that changes in the composition as well as the number of the red corpuscles must exist in some cases of anæmia.

The further progress of the case may be very briefly related. The patient steadily and rapidly lost strength. He was fed upon pancretized milk for a day or two by the rectum to avoid the vomiting which had taken place, and, after this symptom disappeared, again by the stomach.

Dialyzed iron and Fowler's solution were given, but it could not be said that any treatment had the slightest effect. He became very weak, so that he could hardly move in bed without danger of fainting. Delirium, diarrhoea, great dyspnoea upon any exertion, preceded the fatal termination, which took place nine days after his entry, and about seven weeks after he first considered himself sick.

In regard to the treatment it might very naturally be asked why transfusion was not resorted to. In the first place its value might well be doubted on theoretical grounds, since we are evidently dealing with a disturbance of the blood-forming function, wherever that may be carried on, and not with a mere deficiency of blood, which could be rapidly supplied; and, secondly, experience has shown that transfusion is in these cases not only inefficacious, but in some absolutely injurious.

With but very few exceptions those cases of idiopathic anæmia which have recovered have done so under the use of arsenic.

A very careful autopsy was made by Dr. Gannett.

The body was that of a well-built, muscular young man, with a sufficient amount of subcutaneous fat. The surface very pale, with cutaneous ecchymoses.

The brain was anæmic, the sulci being wider and convolutions smaller than usual. On the surface of the pia were several ecchymoses, and others into the substance of the brain, especially in the basal ganglia. About five centimetres of clear fluid in each ventricle.

The pericardium contained fifty centimetres of brownish, opaque fluid, and upon the surface were a few spots of limited opaque thickening, as well as ecchymoses, which were also found beneath the endocardium.

The heart contained a thin, pale, red fluid, which coagulated to a jelly. It weighed five hundred and twenty grammes (seventeen ounces), the muscular structure being yellow, mottled, and flaccid.

The valves were normal except a relative insufficiency of the mitral and bicuspid.

There were ecchymoses in the lungs.

The spleen was small, dense, with but little pulp, and contained several ecchymoses (seventy grammes).

The kidneys weighed five hundred grammes (fifteen and three fourths ounces), and were exceedingly pale and flaccid.

The liver weighed nineteen hundred and twenty grammes (sixty ounces), and contained small nodules of pale, grayish-yellow color, about size of pin's head, or larger.

In the stomach were numerous small ecchymoses, and also patches of an opaque, yellow appearance, somewhat elevated.

The large intestine contained numerous ecchymoses and a few hæmatomata, the size of peas. Over an area of two or three centimetres in sigmoid flexure the mucous membrane was elevated, reddened, and velvety, showing numerous black streaks in which the upper layer of mucous membrane was eroded.

The aorta was of somewhat smaller calibre than usual, very elastic, its wall of about half the usual thickness. The distribution of the intercostals was irregular. There were numerous superficial yellow patches.

By the microscope was found a diffuse, fatty degeneration of the muscular substance of the heart.

In the cortical substance of the kidney was much granular and some fatty degeneration. The vessels of the kidney contained remarkably little blood.

The liver cells in all portions of the acini contained much reddish-yellow pigment and a few small fat drops.

The "nodules" above mentioned are simply anæmic areas.

The marrow of the femur was in places red and jelly-like; it contained, in addition to the usual constituents, a few nucleated red blood corpuscles.

The marrow of the sternum was of a reddish-yellow color, but was not examined microscopically.

### SOME NEGATIVE RESULTS IN SPHYGMOGRAPHY AMONG THE INSANE.

BY F. M. TURNBULL, PH. B., M. D.,

Second Assistant Physician *McLean Asylum, Somerville, Mass.*

MY excuse for publishing results which do not add to positive knowledge is, first, the feeling that in the laudable desire to discover infallible indications in sphygmographic tracings some of the negative evidence and fallacies have been overlooked, and, second, that certain standard works give tracings with statements concerning them which I have not been able to verify.

Tracings No. 1 and No. 2 were taken from Mrs. H., a case of melancholia with hallucinations of sight and hearing and delusions; anæmia; constipation; temperature normal.

Tracing No. 1 was taken January 19th, the pulse being about 120. There was complaint of pain in the abdomen, and laxative medicines were given, but with no effect. She was sleeping two or three hours a night with potass. bromidi, gr. xx., tr. hyosiamini, one drachm, M., given at bedtime regularly. On the 19th she was given chloral hydrat., gr. x., potass. bromidi, gr. xx., M., and at 1.15 the next morning she was given chloral hydrat., gr. xv., potass. bromidi, gr. xx., M.

The above sedatives had very little effect. On the night of January 19th there was a slight movement of

the bowels. Until January 21st the pulse continued rapid, about 120 per minute. On the afternoon of January 20th she was given ext. senna, one fluid drachm, ol. ricini, one fluid ounce, M., and that night had a thorough evacuation of the bowels, passing a large quantity of hardened feces. The following morning, January 21st, there was a general improvement, less restlessness, relief from pain, and the pulse was 80 to the minute. Tracing No. 2 was then taken, and a marked difference found. In tracing No. 1 it will be seen that the shock wave or first event, the diastolic wave or third event (subsidence), and the dirotic wave or fourth event, are the only details apparent. There is indicated the excited and rapid action of the heart, as shown in the frequency and comparative height of the shock wave and sudden subsidence, the lack of tension and incomplete filling of the arteries as shown by the sudden subsidence and dirotism. The prime cause of the peculiar character of tracing No. 2 is evidently the general irritation and disturbance from the presence of impacted feces.

It will be seen by comparing tracing No. 2 with No.

1 that the shock wave is about one half as high, the subsidence slower, and the tension indicated greater in proportion to the height of the shock wave. The immediate cause of the difference seems to be mainly the change in the action of the heart, both as to frequency and force of impulse.

In comparing these tracings, however, what I wish to call particular attention to is the marked change brought about by a dose of castor oil and senna, and the almost exact resemblance of tracing No. 1, from a case without fever, to tracing No. 6, which is copied from one in Bucknill and Tuke's Manual of Psychological Medicine, and given there as "a dirotic pulse (110 beats) in a case of fever." (Page 194, Fig. 8.) A similar tracing is given in an article by Dr. George Thompson (The Sphygmograph in Lunatic Asylum Practice) in Volume I. of the West Riding Lunatic Asylum Medical Reports, as "taken from a person suffering from pyrexia." Nos. 3, 4, and 5 are tracings

from Bucknill and Tuke's Manual (page 299), and are given as typical tracings in acute mania. Nos. 3 and

4 were taken by Dr. Savage, and No. 5 by Dr. Wolf. Dr. Savage is quoted (page 298) as follows: "They bear a strong resemblance to those found in fever and acute diseases, but in maniacal tracings the rate is less and the heart beat more forcible. . . . I have never seen a similar tracing in melancholia."

Now as to "rate" or frequency, Nos. 8 and 9 were taken from a case of acute mania, and the pulse varied from 110 to 140, and I think that a frequent pulse is often found in acute mania.

In the case of Mrs. P. (Nos. 7 and 8) the patient had been without food for a day or so before admission

to the asylum, and was anemic and weak. She drank a considerable quantity of milk after admission. She had chloral hydrate and bromide of potassium in moderate doses as sedatives, and had whiskey, half an ounce three times a day, which seemed to increase the excitement. The time of day when the tracings were taken was not noted at the time, so that the effect of the sedatives or stimulants cannot be determined. No. 7 resembles the "maniacal tracings," but the shock wave is not so high and is more frequent. The shock wave is not much higher than in tracing No. 1, and here I may say I have found the shock wave to vary in the same person, within a few minutes, from slight causes, and also sometimes a difference caused by varying the pressure, and with a new adjustment of the instrument.

No. 8 does not resemble the "maniacal tracings," as may be seen on inspection, but as it may have been modified by the sedatives given, it only shows that we do not always get the typical tracing, owing, perhaps, to some modifying circumstances.

Tracing No. 10 was taken from a typical case of acute mania, in which it was necessary to use restraint.

It differs from the "maniacal tracings" (Nos. 3 and 4) in showing the systolic wave and in its lack of dirotism. The pulse, moreover, was quite rapid, as high as 140 beats to the minute near the time when the tracings were taken, and later in the course of the attack as high as 156. There was also some fever, the fever running latterly up to 102° F.

Tracing No. 11 is from another case of acute mania in which the pulse was slower than in No. 10. In No. 11, June 9th, the systolic wave and also the wave of recoil were quite apparent. The shock wave is not particularly prominent. The difference between this tracing and the maniacal tracings is obvious, there being no dirotism, a lower shock wave, and the systolic and recoil waves being present in the former. June 8th, at noon, potass. bromidi, gr. xxx., tr. hyosci-ami, two drachms, M., was given by enema. This was repeated at bedtime, and again at eleven A. M. on the day when the tracing No. 11 was taken. The tracing was taken at 12.45 P. M. The sedatives did not change the essential character of the tracing, as can be seen on inspection.

In thus comparing tracings Nos. 7 to 11 inclusive, with the so-called maniacal tracings, I think it can be seen that the latter are at least not constant in acute mania, and I think we have in these tracings Nos. 1 and 2, and Nos. 7 to 11 inclusive, partial evidence that we do not have in sphygmographic tracings a reliable means for distinguishing serious affections or organic disease from a slight functional disturbance of the brain and nervous system,<sup>1</sup> but only indications or manifestations of the condition and action of the heart and blood-vessels, which action we all know varies under the influence of every emotion and with every condition of the body or its surroundings as the weather vane moves in the shifting breezes. As farther evidence I shall call attention to the total absence in all these tracings of oscillation, of which Dr. Edgar Holden says, in The Sphygmograph (pages 72 and 73), "Its significance as a feature of a tracing may be thus

<sup>1</sup> By functional disturbance I mean such as may occur in the sane and ordinarily healthy individual.

summed up: Aneurism; severe disorders of the cerebro-spinal system; compression of the artery between the point of observation and the heart; compression by the instrument itself; blood-poisoning, as in Bright's disease or from medicines.

"It may be the measure of tension, and is the measure of pressure as an index of tension. It may be due to a detached valve or other movable body in the large arteries. It may be simply apparent and due to muscular or tendinous tremor."

The italics are mine. From the form of Dr. Holden's sphygmograph and its mode of adjustment to the arm, as shown by the figure in his book, it would seem peculiarly liable to register any muscular or tendinous tremor that might occur, and if his instrument does not eliminate oscillation which may be simply apparent and due to muscular or tendinous tremor, how can he or any one else know that the oscillation is not due to that in cases where there is cerebro-spinal disorder? It is, perhaps, hardly necessary to remind the reader that tremor is a common symptom in cerebro-spinal disorder.

Another way in which the tremor may be imparted to the instruments, and that is from the hands of the operator, unless the wrist support and a firm support for the instrument are used. In using Dr. Holden's sphygmograph the instrument is held in position by the hand of the operator.

In Volume I. of the West Riding Lunatic Asylum Medical Reports, Dr. George Thompson says, on page 63 of his article (The Sphygmograph in Lunatic Asylum Practice), "Let us then notice briefly the pulse tracing which is obtained from general paralytics. By reference to No. 3, taken as a typical example out of a large number of tracings, it will be seen that the line of ascent is slanting and short, while that of descent is gradual and prolonged, and does not display the usual aortic notch, but, instead, presents a number of wavelets which, if counted carefully, will be found to have eight distinct rises and depressions;" and in a footnote adds that eight is only the number of wavelets in the case referred to, and that he has found the number to vary from six to ten. In Bucknill and Tuke (page 320) Dr. Thompson is quoted, and a fac-simile of the tracing given as a typical tracing. I have copied this with tracing paper rather imperfectly. (See No. 12.)

To see if this could be verified, and thinking that perhaps this oscillation had other causes than those to which it was ascribed, the following tracings have been taken with great care and every precaution against muscular tremor, the instrument being supported by the rest for the wrist, which was on a table, the elbow of the patient also resting on the table. No. 13,

from an undoubted case of general paralysis, with extravagant delusions, difficulty in articulation, unsteady gait, lack of coordination, tremor, progressive dementia, etc., was taken June 18th, after the patient had been walking slowly in the gallery. The aortic notch does not show.

In this tracing there is no oscillation, and none of the character which is described as typical by Dr.

Thompson. Other tracings have been taken, but this was selected as the best.

No. 14 is from a case of general paralysis, there having been extravagant delusions at one time, and now a general sense of well being, although the delusions have disappeared; failure of memory, difficulty in articulation, "thickness of speech," irregular, tremulous handwriting, inequality of pupils, good appetite, and is stout. Is taking no medicine. Tracing No. 14 was taken June 18th, after the patient had been sitting in a chair reading; face a little flushed and hands seemed hot, pulse full and strong to the touch. The amplitude of the tracing shows a forcible impulse of the heart. There is the aortic notch, systolic wave, and the wave of recoil. There is no oscillation. Other tracings have been taken.

No. 15 is from a case of general paralysis, taken

after remaining quiet for an hour. At first there were extravagant delusions, impairment of memory, incoherent and illegible letters were written. The patient was emotional.

Later there was much improvement, and the delusions disappeared, but the mind remained weak. There was inequality of the pupils.

July 25th. Signs of incipient catarrhal pneumonia appeared.

December 10th. Symptoms of lung trouble for the most part disappeared; no improvement in physical signs. Coughs less and sleeps better.

July 26th. Has little trouble with cough; general health improved.

January 31, 1881. Little change in physical condition. Mentally weak and emotional; considerable tremor of the lips in conversation; inequality of pupils.

April 13th. Sudden vertigo; anomalous sensations in abdomen; numbness in knee and calves; afraid of falling.

No satisfactory result obtained by examination with aesthesiometer or Paradism; nothing abnormal ascertained: has sensation as of a cord about the knees.

May 6th. Improving; feels well, but avoids going up or down stairs; seems weak in the legs.

The tracing No. 15 shows each event quite marked, namely, the shock wave, systolic wave (aortic notch), and the recoil wave; the shock wave is plainly shown. This may be due to excitement of the heart's action from the patient's attention being directed to it. There is no oscillation.

Tracing No. 16, of Mrs. B., is a typical case of general paralysis, with extravagant delusions of immense wealth, etc.; difficulty in articulation ("thickness of speech"); progressive dementia; tremor of the limbs on motion, and of the lips in speaking; emotional; appetite and body nutrition good; when occupied in reading she does not notice the prick of a pin; has inequality of the pupils.

This tracing is one of quite a number that have been taken in this case. It has the aortic notch, and is free from oscillation as all the others have been. She has taken since, chloral, gr. x., potass. bromidi, gr. xx.,

tr. hyosciami, two drachms, M., sig., h. s. regularly, but this does not seem to have affected the tracing much, at any rate so far as oscillation or the aortic notch is concerned, as other tracings were taken when she had no medicine which showed the notch, and had no wavelets. The tracing No. 16 was selected as one of the best.

To sum up, (1.) we have in a case of melancholia without fever a tracing identical with that of pyrexia, which in its turn "bears a strong resemblance," with some exceptions, to that which is called a maniacal tracing, although Dr. Thompson says, "I have never seen a similar tracing in melancholia."

(2.) We have tracings in acute mania which differ considerably from the so-called maniacal tracings.

(3.) We have tracings of general paralysis in which there is a total absence of wavelets or oscillation, given by Dr. Thompson and by Bucknill and Tuke, as typical and diagnostic, and these tracings generally have the aortic notch.

(4.) We have seen a number of tracings from cases in which there was severe cerebral or cerebro-spinal disorder with no oscillation.

#### Conclusions:—

(1.) That no typical tracing has yet been found in general paralysis, and that the tracings called "maniacal" are instant in acute mania.

(2.) That the tracing of pyrexia, so called, may be produced by other causes than fever.

(3.) That oscillation is at least a very inconstant element in the tracings of cerebral or cerebro-spinal disorder, and that when present it is probably due to muscular or tendinous tremor when no cause can be found other than nervous or mental.

(4.) That the sphygmograph is of little or no use as an aid to the differential diagnosis between the types of insanity, and that its indications may be the same in a temporary functional disturbance of the circulation as they are in serious organic disease of the brain and nervous system.

I am aware that in the portion of this paper which treats of the tracings found in general paralysis I am going over ground that has already been discussed at a meeting of the Medico-Psychological Association, when Dr. Savage said, in a discussion which followed Dr. Thompson's paper, he had not been able to get any tracing that was characteristic of general paralysis.<sup>1</sup> I do not know, however, that he published any of his tracings.

I am also aware that Dr. Thompson's paper was reviewed in the *British and Foreign Medico-Chirurgical Review*, January, 1872, page 23, but although the theory of persistent vascular spasm in general paralysis was dissented from, it was said "we may accept the diagnostic value of the pulse form in early general paralysis."

In a recent article in the *Journal of Mental Science* (No. 117, vol. xxvii.), Teachings of the Sphygmograph in General Paralysis of the Insane, by W. Bevan Lewis, L. R. C. P. Lond., senior assistant medical officer West Riding Asylum, two groups of tracings are given. The first, and smaller group by far, if we can judge from the example given, is almost identical with the so-called tracing of pyrexia, and thus would seem to provide farther evidence besides what I have obtained that other causes than fever may produce this tracing. In the second group, and larger by far, "the most

noticeable features are the sustained tidal wave and extremely shallow percussion element, the latter having as one of its most important factors a feebly contracting ventricle, or at least one whose energy is inadequate to the demands encountered, whilst the former bespeaks the obstruction to the circulation ahead, and the tardy labored force *a tergo*."

These tracings of the second series are compared to the tracings of chronic Bright's disease, "a miniature representation of the same curves," the cardiac hypertrophy being absent in general paralysis. A low pressure was required in obtaining these tracings, and an occlusion pressure below four hundred grammes. Also Garrod's law was departed from, the systolic periods being too short.

He has obtained tracings in epilepsy, chronic mania, acute dementia, as well as in a patient suffering from hydrothorax, representing features almost identical with those he obtained in general paralysis. He invariably obtained a similar tracing in acute dementia. He also has given a tracing "to show the effect of sclerotic tremor upon the pulse curve, possibly explanatory of those minute secondary undulations which often occur in general paralysis."

In all these tracings of general paralysis and those identical with them he considers the factors to be venous engorgement and a feebly acting heart.

It will be seen that Dr. Lewis's observations confirm my second, third, and fourth conclusions, and also my conclusion that no typical tracing has yet been found in general paralysis.

As yet, however, I have not been able to verify Dr. Lewis's results so far as the indications of tension are concerned, and although a feebly acting heart must finally be one of the results of general paralysis, I have not been able to see that the tracing shows it in all cases or even in a majority of the cases, and should think at least that it might not be sufficiently marked during the early stages to be noticeable.

The element of pressure I have found to vary according to the fatness of the wrist or its muscular and tendinous development, — in a stout, muscular person greater pressure being required to obtain a tracing, the pressure being on the tendons and adjacent tissue instead of exclusively on the artery, as one might suppose from seeing records of the pressure used in sphygmography. For this reason, therefore, I have not recorded the pressure used in taking my tracings.

In tracing No. 13, from a marked case of general paralysis, there is indicated a somewhat feebly acting heart to be sure, but the tension indicated is moderate.

In tracing No. 14, from a case of general paralysis, there is indicated a vigorous contraction of the heart, and the tension indicated is slight in proportion to the amplitude. Neither can the tracing be put in Dr. Lewis's first series because there is no diroticism, although there is a wave of recoil which, at first glance, might be mistaken for diroticism.

No. 15, from a case of general paralysis, does not indicate tension and there is a moderate cardiac impulse.

In No. 16, from a typical case of general paralysis, a feeble heart is indicated, but otherwise the tracing could not be put in either of Dr. Lewis's groups.

<sup>1</sup> *Journal of Mental Science*, April, 1875, page 149.

The above tracings, No. 17 and 18, have been appended for comparison, No. 17 being from a case of general paralysis, and No. 18 from a perfectly healthy individual.

## RECENT PROGRESS IN PATHOLOGY AND PATHOLOGICAL ANATOMY.

BY WILLIAM F. WHITNEY, M. D.

### THE INOCULABILITY OF TUBERCULOSIS.

SINCE last year<sup>1</sup> the accounts of several series of experiments bearing upon this subject have been published.

Baumgarten<sup>2</sup> has succeeded in producing an eruption of miliary tubercles in the eye, followed by general tuberculosis, after the injection into the anterior chamber of the eye of a few drops of blood from an animal suffering from tuberculosis. If clean sharp instruments were used, and a solution of atropine was dropped into the eye directly after the operation and for several subsequent days, no appearance of a traumatic inflammation could be seen. The cornea, aqueous humor, and lens retained their accustomed clearness for eight to fourteen days, during which time the blood that had fallen to the bottom of the chamber was entirely absorbed. The eye could not be distinguished from normal. In the third or fourth week tubercles appeared in the iris, in the lower segment of the membrane next to which the blood had lain. The following appearances were similar to those observed by Conheim. This local affection was constantly followed by a general tuberculosis, as had been the case when material from the fresh "pearls" of a tuberculous cow had been used.

Where blood from a healthy animal was injected it was simply absorbed without producing any effect. If the animals were suffering from septicæmia, or otherwise diseased, the blood was harmless, or else caused a greater or less degree of inflammation, often associated with total destruction of the globe and subsequent acute or chronic sepsis or pyæmia. Never, however, with tuberculosis.

The author concludes that these experiments prove the contagiousness of the blood of tuberculous animals, and they refute the view held by many that the reabsorption of the necro-biotic products of an inflammation, resulting from the operation itself, furnish the necessary material for the production of "inoculated tuberculosis."

Toussaint<sup>3</sup> also contributes some positive experiments from which he concludes that the tuberculosis of swine is analogous to the acute tuberculosis of man, while the "pearly distemper" of cattle is always chronic in character.

In both of these classes of animals tuberculosis is easily produced by feeding with tuberculous masses, through inheritance or suckling, or by inoculation with tuberculous particles or blood, and finally from simply living together. He is also convinced of the organized nature of the virus by means of cultivation experiments, and believes he has observed an increase in the virulence.

The question of the nature of the tuberculous virus is also entered into by Deutschmann.<sup>4</sup> He allowed

pure pus from tuberculous individuals to stand for two or three days in well cleaned glasses closed by cotton wool. This separated into two layers, a superficial one of clear yellow serum and a deeper layer of thick rosy pus. These could thus be separately used for experiments.

Microscopic examination of the serum showed it to be entirely free from cells; but on the other hand it contained a considerable number of very small and mobile elements which had the appearance of the so-called monas tuberculosum (the smallest kind of micrococci associated together in twos and sometimes in threes) described by Klebs and Schuller as characteristic of tuberculosis.

Serum was injected into the anterior chambers of three rabbits, which came from pus from three individuals that had been standing two, four, and eight days respectively. At the same time some of the sediment was introduced into the eyes of other rabbits. In every case the inoculation with serum was without effect, while the pus caused an iris-tuberculosis after the ordinary period of incubation. This result was unexpected, but was so constant that no doubt as to it could be entertained.

He further experimented by inoculating the humor aquos from the eye of a rabbit in which iris-tuberculosis had just appeared into the anterior chamber of a sound animal. This fluid contained the monas tuberculosum and pus cells, but no granular detritus from the intact tubercles. This was absorbed without effect. If the disease had existed longer there was found in the aspirated liquid, besides the above mentioned components, numerous cheesy particles. The introduction of this fluid was always followed by an outbreak of the disease.

The inoculation of the humor aquos of a child that was supposed to have iris-tuberculosis, and in which the monas was considered to be present, was without effect.

The author considers that there are three ways of explaining the relation of the organisms found in the serum to the production of the disease. (1.) The micrococci have no connection whatsoever with the tubercular virus. (2.) The micrococci are the carriers and disseminators of the poison, when they develop in a proper soil (the sediment of pus). (3.) The micrococci possess specific action, but that they occur in these experiments under such unfavorable conditions of life and reproduction that they are overpowered by the organism into which they are introduced and produce no harmful working. And it is only when there is injected with them a proper food for their support that they can gain sufficient footing to produce their specific action.

Tappeiner<sup>5</sup> was unable to produce tuberculosis in dogs by feeding them on the sputa from tuberculous cavities, and concludes, therefore, that the gastric juice of the dog is in a condition to destroy the virus. He holds that it is probably the same with man, and that the air passages are the principal way by which the poison obtains access to the system. Portions of phthisical sputa being dried, mixed with the dust of the air, and then inhaled.

Orth<sup>6</sup> takes up the question of the relation of phthisis and tuberculosis. In the tuberculosis of animals

<sup>1</sup> Vide Boston Medical and Surgical Journal, vol. cv., p. 75.

<sup>6</sup> Berl. klin. Wochen., 1881, No. 40. Centralblatt, 1882, No. 9.

produced either by feeding, inoculation, or inhalation, there occurs a diffuse cheesy affection especially in the lungs, which corresponds to certain forms of phthisis, especially in children. Since in men the military eruption in more than half of the cases is accompanied by phthisis of the lungs, and an outbreak of tubercles in the peritoneum and pleura is a marked consequence of phthisis, therefore the author is disposed to regard phthisis and tuberculosis as an aetiological unity. The separation of the inflammatory phthisis from the tuberculous phthisis, as urged by Virchow, is still to be preserved in its descriptive anatomical meaning; the aetiology of the process is, however, always the same. The author wishes to have the word "tuberculosis" laid one side, and the term, "scropholosis" employed in its stead. The nodules developed in the course of the disease are to be distinguished by the name of "scrophuloma."

#### CONTRIBUTIONS TO THE ANATOMY OF MILIARY TUBERCLE.

Arnold has made a series of studies upon the anatomy of tubercle occurring in the various organs commencing with the liver.<sup>1</sup> In this there are to be distinguished the miliary and larger conglomerated form. The latter have been considered for a long time as especially associated with the gall ducts. This was not only confirmed, but it was also shown that in most of the miliary tubercles as well, numerous and apparently new formed ducts were to be met with. The number of these canals varied greatly, in some tubercles there were but one or two, while in others they were very numerous, lying close together, tortuous in their course and sometimes branched. The epithelial character of the cells lining their walls, as well as their relations to the larger ducts into which they could at times be followed, left no doubt as to their nature. Besides these there were found liver cells either isolated or in rows lying amongst the lymphoid tissue in the periphery of the nodule.

The author is inclined to distinguish three varieties of miliary tubercle in the liver: First, those composed entirely of lymphoid tissue and having their seat in the sheaths of the small arteries and veins; second, those composed of the same tissue and situated in the walls of the gall ducts, while the peculiarity of the third variety consists in the presence of these newly formed canals. All three varieties may be found in the same case, so that their distinction is chiefly of anatomical interest. The third variety is also found in the liver in cases where there is simple cheesy degeneration or other degenerative processes in other organs, as well as in cases of general tuberculosis. The tendency to undergo a cheesy degeneration helps to distinguish these new ducts from those formed in the course of chronic interstitial inflammation.

Another change which these canals undergo ends in the production of giant cells. In some places the epithelium becomes loosened, forms an opaque mass, which finally disappears leaving only the fine connective tissue sheath. The ducts then assume an irregular form, the walls are unsymmetrically distended, or the canal unequally dilated and elongated in various directions. The whole process is closely allied to the cystic enlargement occurring in other glands. In other places the epithelium retains its polygonal form, or is flattened and elongated, becoming even spindle

shaped. The relation of these cells to the wall is peculiar. Here they clothe the surface equally, there they are heaped together at one point or pressed into the middle, while the contents of the tube forms a yellow, glistening, finely granular mass of gelatinous consistency. Thus appearances are produced similar to those seen in giant cells, and many of them are undoubtedly formed in this way.

Incidentally attention is called to the normal existence of small masses of lymphatic tissue in the connective tissue about the gall ducts. The author shows that the occurrence of lymphomata found in the liver after scarlatina, typhoid fever, measles, and various acute infectious processes must be dependent upon the existence of this, while the part which it takes in the tuberculous processes is probably of still greater importance.

*Tuberculosis of the Kidney.* — In his second article<sup>2</sup> Arnold takes up this subject. Tubercle occurs in the kidney in the miliary, submiliary, and larger forms, or occurs as an extended infiltration. It appears as an accompaniment of general acute tuberculosis, or it may be secondary to chronic affection of other organs, or as a direct continuance of the so-called local genito-urinary tuberculosis. The largest tubercles are found when the lung, or intestine, or genital tract is the primary seat of the disease.

In the miliary form, and in the periphery of the larger cheesy nodules, there is to be met with a new formation of tubes, singly or arranged in groups, looking like the urinary tubules, yet differing considerably from them.

They are narrower, have no lumen, and have several rows of cells, the nuclei of which take coloring matter strongly. They forcibly suggest the tubules found in an adenoma of the kidney, and their analogy with the new formed bile ducts, already described for the liver, is a very close one.

They also undergo a similar change. The cells at the periphery become flatter and elongated, and the lumen of the canal is filled with a finely granular, gelatinous material. The tubes may become dilated here and there, and assume irregular shapes, which, upon section, correspond to the appearance presented by many of the giant cells. The malpighian bodies, often found in the tubercles, also undergo a cheesy degeneration. The capillary loops first become indistinct, and finally disappear as do the cells lining the capsule, which are converted into a granular mass. These may also present the look of a giant cell. Finally the lymphatic tissue surrounding the capsule takes part in the metamorphosis, and the nodule becomes a uniform cheesy mass, with only a few lymphoid cells left in the periphery.

Some of the tubercles undergo a fibrous change. This begins in the lymphoid cells surrounding the tubules, which assume a spindle shape, with their long axes radiating from the opening of the tube, and separated from each other by a varying quantity of light, slightly striated material. At the same time the epithelium in the interior of the nodule is transformed into a granular mass and disappears as the change in the surrounding tissue advances. The tunica propria at last vanishes, and when this has taken place the whole nodule presents a uniform fibrous appearance. If the fibrous tissue in its advance presses unequally upon the tubules, portions of these are cut off and irregular

<sup>1</sup> Virchow's Archiv, Bd. 82, s. 377.

<sup>2</sup> Virchow's Archiv, Bd. 83, s. 239.

bodies are left looking like giant cells, and sending prolongations into the surrounding newly formed tissue.

The author wishes, however, to distinctly assert that he does not consider all giant cells, either in the liver or kidney, to be formed in this way, but will show when considering tuberculosis of the lymph glands in what other ways they may be produced.

*Tuberculosis of the Testicle.*—This has been investigated by Waldstein<sup>1</sup> in a series of cases furnished by the clinic at Heidelberg. As the result of his investigations it appears that the cheesy nodules, which are to be seen with the unaided eye, are formed by changes which have their seat either in the interstitial tissue in the interior of the canals or in the walls of the same.

In the connective tissue of the organ scattered infiltration of small cells is met with, occurring first about the vessels, especially at the nodal points where the branching takes place. This is distinguished from the early stage of a simple inflammation by its dispersed, circumscribed character. At the same time an infiltration and thickening of the wall of the canals takes place, which, however, may be independent of this. There is also often found a hyaline thickening of the wall, which, however, alone is not characteristic, as it appears equally in the walls of the small arteries in the other organs, and even in testicles where there is no suspicion of tuberculosis.

The changes in the interior of the canals can be shortly described by saying that the epithelium is either loosened from the wall, fatty degenerated, squeezed into the middle and atrophied, or the portion next the wall is alone changed, while the central cells become rolled together, and later metamorphosed into a so-called giant cell.

The existence of nodules has been made a point of great importance in the diagnosis of this disease, and they appear to be of two sorts. One composed entirely of round cells, and the other of larger and more epithelioid like cells, mingled with which are the ordinary round cells, and others of a more or less spindle shape. The diagnosis between tuberculosis and cheesy orchitis is not always clear, even when the clinical aspect of the case is considered.

*Tuberculosis of the Lymph Glands and Spleen.*—Arnold in his last article<sup>2</sup> gives the result of his investigation of material of ninety cases partly from autopsies, and partly from surgical operations.

He concludes that the tuberculous process begins in the lymph glands, as in other organs, with the nodular formation of granulation tissue, the cells of which assume later an epithelioid character, with the formation at the same time of multinuclear and giant cells. In the further course of the process there usually appears cheesy, more rarely hyaline or fibrous, degeneration. These three forms of degeneration can also occur in the inflammatory new formation without the previous epithelioid change. Therefore the author does not consider the reticulated tubercle with its epithelioid and giant cells as a particular form, but only a phase in its degeneration. Just as little does he believe that the development of the tubercle commences with the formation of a giant cell, as many have considered to be the case, and he adds his testimony to that of others against the diagnostic worth of the presence of these bodies.

In scrofulous glands, which are often regarded as simply tuberculous, Arnold found that in the commencement of the process an extended hyperplasia was present, while a new formation of nodules composed of small round cells could not be detected. Later there occurred, however, nodules of epithelioid cells, which subsequently became cheesy. The process extends over a greater portion of the gland from the commencement than in the case of tuberculosis. The epithelioid and giant cells are found in both equally, but in the tubercle they are generally confined to the nodules, while in the scrofulous glands they are everywhere equally distributed.

In regard to tuberculosis of the spleen there is no doubt but that it commences in the malpighian bodies as in the follicles of the lymph glands, and undergoes the same degenerations. It can also have its point of origin in the adventitia of the vessels, and more rarely in the pulp.

## Hospital Practice and Clinical Memoranda.

### A CASE OF PUERPERAL PERITONITIS.

SAMUEL AUG. FISK, M. D. (HARV.), PONCHA SPRINGS, COLORADO.

MRS. M., an American, twenty-four years old, was confined with her third child, a girl, head presenting, early in the evening of Saturday, February 4th. She was attended by a midwife. The labor was easy and rapid, lasting only about three quarters of an hour. The after-birth came away almost immediately, without any interference from the midwife. The placenta and membranes were said to be whole, and there was not any excessive bleeding. The midwife left in a couple of hours after the labor and Mrs. M. slept the night through.

Mr. M says his wife suffered a slight laceration of the perineum at the time of her first labor. It must have been very slight, for the perineum is now intact. Previous to this labor she had been constipated, but was in good general condition. She found, however, that she did not rest well at night if she ate any supper.

Sunday, February 5th. She was bathed early in the morning and her clothes were changed, and as nearly as I can learn was exposed to the cold while bathing, by the opening and shutting of doors into cold rooms. Her diet was toast and tea, of which she partook heartily. She rested quietly all day, and the child was put to the breasts, as in fact it had been the previous night.

Monday, February 6th. Diet, toast and tea, some California canned cherries, also some canned cove oysters (Field's brand). Nursed the child. P. M. crampy pains in abdomen.

Tuesday, February 7th. I was called at 3.30 A. M. and found the patient suffering from intense pain in the abdomen. Abdomen somewhat enlarged and tender to pressure, especially in the iliac fossae. Pulse full and rapid, and respirations rapid. R. Squibbs' tr. opit comp. (diarrhoea mixture) c. e. iv. Sinapisms and hot fomentations locally. Pain was relieved, and she went to sleep. At eleven A. M., she was given an enema of soap-suds, and a considerable mass of hard, dark faeces came away. Her bowels moved twice that

<sup>1</sup> Virchow's Archiv, Bd. 85, s. 397.

<sup>2</sup> Virchow's Archiv, Bd. 88, s. 111.

day, and once the day following. This eased her. She complained of sore nipples from the child's sucking. No cracks visible. The milk came on this day, and her lochia were abundant and not offensive.

Wednesday, February 8th. She was bathed. At noon she ate a third of a can of oysters. All this without my knowledge. Nursed her baby all night.

Thursday, February 9th. About one A. M. pains returned, but not so severely as on Tuesday A. M. Mr. M. put mustard plasters and hot cloths on her abdomen, and it eased her so that she went to sleep. I was called in, a second time, at nine A. M. Found pulse 145; temperature 103.5° F.; respiration 42. Respirations thoracic. Abdomen swollen, tympanitic, and tender to pressure especially over the pubes and iliac fossae. Milk present, and she nursed her child all through the day. Lochia present and not offensive. R. Quinine sulph. (in sol.) 95 gm. every three hours. Flaxseed poultices over abdomen and changed repeatedly. Also gave a vaginal injection qts. iii. warm water with three teaspoonful sat. sol. of carbolic acid. Diet: milk, ice, whiskey. Afternoon. Ringing in ears. Temperature 101.2° F.; pulse 130; respiration 26. Lochia present and normal. Milk still present.

Friday, February 10th. About one A. M. pains returned, and her husband put on mustard plasters and hot cloths. About four A. M. they gave a vaginal injection as it had eased her so much the day before, but it gave no relief this time. Her tongue became stiff, chin dropped, and she gasped for breath. She was rubbed with whiskey and camphor. I was called again at 5.30 A. M. and found her very low; pulse 132 and thin; temperature 105° F.; respiration 45 and shallow. R. Spts. camphor, gtt. x., and whiskey in teaspoonful doses repeatedly. Sinapisms to abdomen. Also Squibbs' mixture c. c. iv. Ten A. M. I had a consultation with Dr. C. B. Underhill (Harv.) of Salida. And had Mr. M. telegraph for her parents to come from Kansas.

*Consultation. Results.* — Lacerated cervix uteri. Tender spot (on pressure) on anterior vaginal wall in front of cervix. Abdomen greatly swollen. Tympanites. Tenderness on slight pressure over pubes and iliac fossae. Respiration thoracic. Pulse rapid, thin, and shreddy. Temperature, as earlier in the morning. Respirations shallow and rapid. Milk stopped. Lochia present, but scanty, not offensive. Legs extended; not flexed. Prognosis. Death within twenty-four hours. We ordered: Poultices for abdomen, to be changed repeatedly. Vaginal injection with carbolic acid. R. Quinine sulph. .13 and morphia sulph. .008 in wafers every two hours. At twelve noon she had a fainting turn; I was called in and exhibited spts. camphor, and whiskey freely.

Afternoon, five P. M. Pulse 132; temperature 104.8° F.; respiration 26. Gave a vaginal injection. I stopped the administration of morphia as directed. I watched with her that night, giving milk and whiskey. Poultices were changed frequently. I gave a causet of quinine .13 and morphia .008 at eleven o'clock, and another at three A. M. She slept quietly. Respirations were in series of three at a time. The first long, the other two rapid and shallow, and the interval between the series was seven seconds (Cheyne-Stokes?).

Saturday, February 11th. Pulse 132; temperature 103.4° F.; respiration 18. She was feeling so well that we changed her clothes throughout taking care to

have the room warm. Milk returned in abundance. Lochia still present and normal in odor. I drew the urine with a catheter, and gave a vaginal injection with carbolic and warm water (about 105° F.). Diet, milk; but the doses of whiskey had to be moderated as they flushed her and affected her head. Afternoon, 4.30 P. M. Pulse 132; temperature 102.5°; respiration 24. The milk was still present. Abdomen still swollen and tympanitic, and the tenderness was extending upwards especially on the right side; she spoke of slight pain under her ribs on the right side. She had not had any morphia since three A. M. The quinine had been continued. I was called out of town, and gave directions to give a powder of morphia if the pain became sharp. They gave morphia sulph. .008 at five and again at seven P. M., and at one time put the raw mustard directly on the skin. When they took it off, the skin came with it, but she did not feel it. At ten P. M. I returned. Found the pulse thin and shreddy, the respirations shallow and frequent, carphologia. She was in great pain. Morphia sulph. .008, and again at eleven o'clock. Also sinapisms. Pain relieved. Pupils only moderately contracted. She went to sleep. I watched with her again that night. Administered milk and whiskey freely, arousing her to give them. The respirations as on the previous night but much weaker. She grew steadily worse, and it became very difficult to arouse her to take stimulants. Pupils were only moderately contracted, and her respirations were twenty-four to the minute.

Sunday, February 12th, 2.30 A. M. She could not swallow any more. Pulse stopped at the wrist. The head was thrown back. Respirations were forced. The eyes became fixed. The chin dropped. The cheeks were sunken. Tongue was stiff and dry, and heavily coated, and her respirations came with a rattle. She was unconscious, and could be aroused only momentarily by the piercing, beseeching cries of her husband. Involuntary micturition. I administered in succession three syringes full of ether hypodermically, and followed them by repeated subcutaneous injections of whiskey. Her arms were rubbed with whiskey, and hot bottles were put to her feet. Her pulse came up and the respirations were restored. She then remained in an unconscious stupor from four until eight A. M. 7.30 A. M. Temperature 106.7° F. (in axilla); respiration 30, and heavy; pulse 132, moderately full, mild delirium and nervous twitchings. With her husband's consent I put on wet packs, and changed frequently. In about three quarters of an hour the temperature fell to 102.2° F. The respirations became easy and the pulse full. Spirits frumenti by enema. Mrs. M. went into a gentle sleep. The diet was milk iced, and I ordered whiskey as much as she could bear. Five P. M. Pulse 132; temperature 101.5° F.; respiration 20. I again put on a wet sheet as the respirations were becoming heavy. It eased her very much. I again watched with her. Respirations as on previous nights. She rested quietly without any opiate, and from this time on I gave up the administration of morphia. Milk and whiskey were administered frequently. She rested quietly, excepting that she became uneasy, and her vitality seemed less, about two A. M., as occurred every night I watched with her.

Monday, February 13th, nine A. M. Pulse 156; temperature 102.8° F.; respiration 32. Diet had been milk, and whiskey had been administered. R. Veratrum viride (Norwood's tincture) twenty drops, also quinine

sulphatis .13 in wafer. 12.30, noon. She began vomiting, and the vomiting lasted for three hours. She must have vomited between a pint and a quart of coffee-ground mucus, and in it was the pellet of quinine undigested. Five p. m. Pulse 86; temperature 101.2° F.; respiration 20. Greatly prostrated. Abdomen lax and non-tympanitic. Gave an enema of whiskey. I again watched through the night with her. No medicine administered, but I gave her a little whiskey by the mouth, and one enema of beef tea about midnight and another at seven a. m.

Tuesday, February 14th, nine a. m. Pulse 130; temperature 102° F.; respiration 30. She had spent a quiet night and rested well. Her parents had come, and she was allowed to see them. Abdomen lax, non-tympanitic, and not tender to pressure. On account of the sensitiveness of her stomach quinine was not given through the day. Milk was given cautiously and only in small quantities. R̄ Veratrum viride gr. v. at eleven o'clock and again at five p. m. This last nauseated her. Five p. m. Pulse 138; temperature 104° F.; respiration 36. That night her husband said that Mrs. M. was delicious, and at three a. m. she was given R̄ Morphia sulph. .008. That afternoon she had a voluntary defecation, soft and natural in color.

Wednesday, February 15th, nine a. m. Temperature 103° F.; pulse 150; respiration 35. I stopped the administration of beef tea, because I found that it flushed her and acted too much like a stimulant. I was giving very little whiskey and no quinine. She took milk well. She was feeling nicely, and she had her clothing changed. Found a bed-sore over her sacrum.

Friday, February 17th, nine a. m. Pulse 120; temperature 102° F.; respiration 28. No cough; no pain referable to her chest. The right cheek was flushed.

*Physical Examination.*—Percussion showed dullness on her right back from the spinal column around into the axilla and downwards from the end of the scapula on the back to the fourth rib in the axilla and the fourth intercostal space in the mammary line. There was a flat spot in the axilla about at the fifth rib.

*Auscultation.*—Occasional moist râles near the spinal column. A friction sound at the seat of flatness. Occasional sibilant râles over the area of dullness, and over the area of flatness bronchial breathing.

I ordered flaxseed poultices to the chest, to be changed repeatedly. I also resumed the administration of quinine .065 every two hours. Whiskey to be pushed, and a milk diet. Five p. m. Pulse 126; temperature 102.5° F.; respiration 30. She has not had any cough nor any pain in her chest.

Saturday, February 18th, nine a. m. She had spent a quiet night. Area of dullness about as yesterday, except that the area of flatness extended more forwards towards the mammary line. Auscultation as on previous morning.

She was taking milk well and relished it. She was lying on the right side partly to ease the respirations, and partly because of the bed-sore over sacrum. Five p. m. Temperature 103.5° F.; respiration 26; pulse 126. In a stupor. Ten p. m. She had had a peaceful sleep and awoke feeling bright. She spoke especially of her refreshing sleep.

Sunday, February 19th, nine a. m. Temperature 101.5° F.; pulse 142; respiration 36. She was feeling

decidedly better. She complained of pain in right side on breathing.

*Physical Examination.*—Showed less dullness along spinal column and the breathing becoming vesicular. Friction sound as above, and fine moist râles all over the lower back. Breathing less bronchial than yesterday.

Monday, February 20th. Poultices on back and chest. Area of dullness diminishing in the back from the spinal column forwards, but the area of flatness increasing forwards in mammary line under fourth intercostal space and down to liver flatness. Friction sound as above, respiration clearer along the back, especially near the spinal column, *crepitations redue* in the back and axilla. She spoke of a tingling sensation over whole body.

*Analysis of Urine.*—Color normal. Specific gravity 1018. Reaction slightly acid. Urea greatly increased. (Crystals of nitrate of urea formed almost immediately, and, in testing for albumen, crystals formed a layer at point of contact with acid.) Albumen a very slight trace. Chlorides slightly diminished. Sediment abundant and cloudy. It contained amorphous urates in abundance. Frequent pus corpuscles. Circular and pavement epithelium, separate cells and in clusters (vaginal), mucus, shreds, and casts.

Five p. m. She has been taking milk freely through the day. Tongue clearing up. I noticed fine milary vesicles over chest, back, and abdomen. Pulse 120; temperature 100° F.; respiration 28.

Wednesday, March 1st. Pulse 120; temperature 99.5° F.; respiration 24 and easy. She is eating well, feels well, except that the bed-sore has suppurated and troubles her. I have had poultices applied to it for several days. She sits up for a while every day, and has been doing so since Sunday. No pain on respiration, but she coughs a very little. Expectoration is a light mucus.

*Physical Examination.*—Shows percussion normal except in a limited area in axilla which is very slightly dull. No râles are elicited even on forced inspiration and with cough. Respiration vesicular, but slightly suppressed in axilla. Abdomen lax and normal. No tenderness on pressure. Vaginal examination showed that the cervix uteri was normal in size and hard. A slight lateral laceration to the right. No tenderness on pressure anywhere in vagina.

There is no milk in the breasts. Child is doing well on cow's milk and water, half and half.

*Remarks.*—In reporting this, the first and only case of puerperal fever that I have ever treated, I am conscious that I am laying myself open to criticism in regard to my treatment. For instance, intra-uterine injections, which are considered almost a *sine qua non* in the treatment of this class of cases, were not employed here, and most of my professional brethren will have suggestions of methods which might have been employed. My reply to objections must be that I find it impracticable, in this small town in the heart of the Rocky Mountains, to do many things in my practice which would be considered essential in the East; that, further, as Horace puts it, "*Nam vitis nemo sine nascitur*," and, finally, that my patient has made a good recovery from an unusually severe and protracted sickness.

This case was autogenetic. There was no possible source of contagion that I can learn of. There have not been any other cases in town, nor, in fact, have

there been any of the zymotic diseases recently. The house is cleanly, and is situated on high and dry ground; further, the woman is very cleanly in her habits. Whether the origin, in this case, was due to septic absorption through a lacerated cervix uteri, or whether it was due to her bathing in a room where doors were open to the cold, the day following her confinement, it is difficult to tell.

I found that the administration of beef tea was followed by flushing of the face, an increase in strength and rapidity of the pulse beat, and I therefore stopped it. Since then my attention has been called to the article of Mr. Mastermann, in the *Lancet* for October, 1880, and also to that of Dr. Neale in the *Practitioner* (November, 1881), in which they show that beef tea has an analysis similar to urine, and that it is a stimulant and not a food.

I cannot but feel that Mrs. M.'s life was saved (Sunday, February 12th) by the frequent hypodermic injections of ether and whiskey on the one hand, and by the wet pack on the other, when her temperature (in axilla) was 106.7° F.

The relaxation of her abdomen, and the disappearance of the tympanites, dated from her vomiting spell on Monday, February 13th, and although greatly prostrated by it, she soon rallied and improved from that time.

The pneumonia and localized pleurisy were discovered not through any subjective symptoms, but because I was apprehensive that they might exist.

## TWO CASES OF CHRONIC OTORRHOEA

PRODUCING CARIES OF PETROUS PORTION OF TEMPORAL BONE, ONE WITH CEREBRAL ABSCESS, THE OTHER WITH GENERAL MENINGEAL INFLAMMATION AND MENINGEAL ABSCESSES.

BY JAMES L. QUINN, M. D., EATON, OHIO.

ON November 27, 1879, F. C. came to my office for treatment for chronic otorrhœa. He was a young man aged nineteen years, of fair physical development, but his mother had died of consumption, and his father was at this time suffering from the same disease, and died from it in a few months. The otorrhœa in the case of Mr. C. had lasted from childhood, and dated back to an attack of scarlatina. When he presented himself to me for treatment the most marked symptom was a very offensive discharge from right ear with almost total deafness on the same side. No considerable pain, except at times when abscesses would form in the ear, and at these times the chronic discharge would cease until the abscess would break. The pus would be thick for a few days, and then become thin and offensive again. The odor was so great that the room where he slept would be full of it in the morning. He had had occasional treatment, but it was never persisted in until much benefit was obtained. The offensive discharge had been thus for about three years. On examination could detect an ulcer in the soft parts, situated in the upper and anterior wall of the external auditory canal. The drum of the ear appeared to be sound, and no air passed through it on inflating the internal ear through the Eustachian catheter. Prescribed for him

|                         |     |
|-------------------------|-----|
| R. Atropia sulph., grs. | iv. |
| Acid carbol., gttss.    | x.  |
| Aq.                     | 3ij |

The ear to be washed out with a syringe and warm water three or four times a day, and a few drops of the above solution dropped in. Gave him no constitutional treatment. In addition, I syringed the ear myself three times a week, and inflated the internal ear. This treatment was continued about three or four weeks, when I added ten grains of nitrate of silver to the above solution, and went on with treatment same as before until the end of two months, when I had the satisfaction of seeing that the discharge itself was much lessened in quantity and no longer offensive; his hearing had been improved from three inches to three feet in hearing the tick of a watch. I was very much encouraged, thinking that I would soon be able to discharge my patient, if not entirely cured at least so much improved that he would have little further trouble from his infirmity. About this time, however, he discontinued attendance, and I did not see him for two weeks, when he returned with the disease aggravated from taking cold while skating. Abscesses had formed again, and the old offensive discharge was re-established, and this time it resisted treatment, and, on account of the serious illness of his father, he did not come very regularly to my office.

On March 25, 1880, I was called to visit him, and found him suffering from severe pain in the right side of head and right ear; there was no fever, and the pulse was normal. I supposed he was suffering from an attack of neuralgia, and prescribed for him two grains of quinia every four hours, fully expecting in the morning to find him much improved, but, contrary to my expectations, he was no better, but having no especial reason to change my mind in regard to the diagnosis I continued the treatment, and gave him a small dose of calomel at night which operated very freely next morning, but still no improvement in head symptoms. His temperature was from half to three fourths of a degree below normal and pulse 60, sometimes falling to 50 per minute, but in other respects normal, tongue heavily coated brown; no appetite, and could not sleep on account of pain, which was located in right temporal region. Pupils normal, and respond readily to light. The pain in head gradually extended from temporal region to vertex, and was very severe. I now gave him tincture of acouite, and blistered the back of the neck, and both before and behind the ear, but without any relief to suffering. The offensive discharge from ear continued all the time, except for about twenty-four hours, when it again started up as profuse as ever. Nitrate of amyl was tried for the pain in head, but seemed to aggravate it, and it was discontinued. I put him on iodide of potassium which was continued until death, but at no time did I have much hopes after the tenth day of the disease of benefiting him by treatment. After the second week I was obliged to give morphine at night in order to procure any sleep, and only when under its influence did the temperature and pulse go above the normal condition except on the last day, and then, though he had had no morphine for forty-eight hours, his condition was as follows: Pulse 86; temperature 100° F; respiration 24. Partially comatose, but can be aroused sufficiently to attempt to protrude his tongue, which is covered with a slimy secretion and red at tip. Secretions collect in throat and are swallowed. Some paral-

ysis of muscles of deglutition. Pus appears to pass down Eustachian tube into throat and has caused some pharyngeal inflammation. Pupils neither contracted or dilated, but do not respond to light. No paralysis of muscles of tongue nor of the extremities, but extreme weakness has existed for a week. Speech has been defective for some days, and this morning he was unable to articulate intelligibly, though he could hear and understand what was said to him, and made effort to answer. I had diagnosed disease of brain, arising from caries of temporal bone, which was verified by the autopsy, which was made on April 14th, the day after he died. At the autopsy were present Drs. Stephens, Welsh, Small, Bruce, Campbell, Michael, and myself.

On removing calvarium we found a large abscess situated in the middle lobe of right hemisphere of cerebrum, a thin layer of brain tissue intervening between the pus and bone, which ruptured. The abscess contained two ounces of pus, thick, dirty, and extremely offensive. The lower part of abscess lay on the petrous portion of temporal bone, in which there was a carious perforation one quarter of an inch in diameter over the semicircular canals; and external to this were several patches of blackened, diseased bone. The mastoid cells were also diseased, and carious bone was found in them. The abscess seemed to connect with the large carious opening, and probably discharged some of its pus through it and into the throat. The arachnoid contained a much larger amount of serum than normal. No special congestion and no inflammation of membranes of brain.

CASE II. Was called on April 4, 1880, to visit Alice W. She was about twenty-two years old, and had suffered since childhood from trouble with her ears, sometimes one and sometimes the other giving her the most pain, but for three years the right ear had been principally affected, and this with a chronic, offensive discharge, thin, and watery in character. This, as in the first case, dated from an attack of scarlatina. The discharge was so offensive that the whole room was full of it. It was sickening on coming close to patient, and was so profuse that the pillow on which she lay was saturated. When I first saw her she was complaining of pain in right ear and in temporal region. Some vertigo, tongue coated and dry, no appetite, bowels not moved for some days; pulse 90; temperature slightly above normal. Gave her hyd. sub. mur. five grains, hyd. cum creta, ten grains, at bed-time, which moved her bowels freely next morning. I then gave her quinia sulph., two grains every four hours, and aconite, five drops every four hours; I also prescribed atropine, same as in first case, to be dropped in her ear four or five times a day. I omitted the nitrate of silver. The first prescription was discontinued at the end of first week, as it did not appear to be of any benefit whatever. I then gave her bromide of potassium in ten grain doses, with no better result. Blisters were applied on neck and behind the ear, and kept discharging freely. At the end of ten days the heat of body had increased very much, but she was so restless that it was impossible to get the temperature. The pulse ran up to 120, and there was violent delirium, with loss of ability to articulate intelligibly. I now put her on ergot, thirty drops, tincture of aconite, five drops, every four hours, under which she began improving slightly, in some respects at least. She regained, to some extent, her ability to articulate words, but only a few short ones, and she was never

entirely conscious at any time after delirium first set in. There was partial paralysis of right arm, but no change in facial muscles, or in pupils. Her delirium was so violent at this time that it was almost impossible to keep her in bed, and she required constant watching, and required some one to be continually pressing with the hands on top of the head, to which point the pain had gradually extended by the end of a week, and in ten days to the back of head. There was also decided opisthotonos, her head being thrown back between the shoulders; when she turned on her back she appeared to touch the bed only with her heels and back of head.

She died on the 18th of April, fourteen days after I first saw her. During the forty-eight hours previous to death the ear appeared to be discharging through the Eustachian tube, as she spit up pus, and there was some inflammation also of pharyngeal mucous membrane. The right ear also discharged all the time freely, externally.

Autopsy made eighteen hours after death. Present, Drs. Small, Bruce, Michael, Campbell, and myself. On sawing through the bone a large amount of blood escaped, and we found on removing calvarium that it was from a remarkably congested condition of the meningeal vessels. There was also a general meningeal inflammation. As we removed the brain found an abscess situated near the apex of petrous portion of temporal bone, and extending backwards to the medulla. The abscess was in the meninges. There were several other small abscesses at other points in the membranes. There was also a carious opening in the petrous bone, communicating with internal ear; the disease in the bone corresponded to the point where the large abscess began. Cut down into the bone and found carious condition of bone in semicircular canals and in mastoid cells.

These two cases have been of much interest to me on account of their intimate connection and dependence on chronic disease of the ear. In a country practice we do not often meet with such, and more rarely have opportunity to verify by post-mortem examination the exact condition of the temporal bone after a long-continued chronic otorrhea. The disease of the bone and consequent disease of membranes and of the brain itself, are only part of the dangers of allowing otorrhea to run on without treatment, hoping for a spontaneous cure, or, as it is frequently spoken of in the country, expecting the child to outgrow the disease. No doubt many of the simple diseases of the external auditory canal do head spontaneously; but many that finally result in permanent deafness might have been cured in their early stages by judicious and persistent treatment, the hearing restored, and perhaps lives saved. In the first of these cases I was reasonably well satisfied that there was caries of the temporal bone, but the exact location and extent I was not able to determine, but the fetid discharge, unaccompanied with perforation of the tympanum, left no doubt of the diseased bone. But at one time there was so much improvement that I felt in good hopes that the injury was limited, and would eventually be healed. I was disappointed, and the post-mortem showed injuries that it was impossible to treat to a favorable termination. In the second case I had never prescribed until she was taken down with the acute symptoms. I never examined her ear carefully, as no opportunity offered for me to do so; and I did not know whether the drum was perforated

or not. I was guided entirely by the history of the case given me by the patient herself and by her mother. I leave the cases without further comment, as the report was necessarily long, and too much space has already been occupied.

## New Instruments.

### A HEAD SUPPORTER.

BY C. E. WEBSTER, STUDENT OF MEDICINE.

It is often necessary in surgical practice either to entirely remove the weight of the head from the spinal column, as in caries of the vertebra, or to restore and maintain it in a normal position, as in conditions dependent on abnormal muscular action. For these purposes various contrivances have been used. The Taylor head supporter and its modifications and Sayre's jury-mast are perhaps the best known and most typical. All are open to some objection. They may annoy the patient by being very conspicuous and awkward. They may be painful to wear, may hold the head in a constrained position, restrict to an unnecessary degree its freedom of motion, or afford insufficient support.

The apparatus herein described was made by the writer with the view of obviating as far as possible these disadvantages. The necessity for complete support of the head was never lost sight of. The next object considered was the comfort of the patient. The apparatus is not cumbersome or very conspicuous, is easily removed, perfectly fitting, and permits great freedom of motion.

It consists of two parts, *a* and *b* of the cut. The

part *a* may be made of copper, steel, or vulcanized rubber. Copper from one thirtieth to one twenty-fifth of an inch in thickness is about the most convenient material. A plaster cast should be taken of the lower part of the head, and the sheet copper hammered or swedged to fit the cast. *It must fit perfectly*, in order that the pressure may be as uniformly distributed as possible. This head-piece should be tinned or silvered on the inside to prevent corrosion, and lined with thin

felt or flannel to protect the skin from the uncomfortable chill of the metal and facilitate the evaporation of perspiration. To still more facilitate evaporation the metal may be perforated with numerous fine holes. It should be stiffened by a boss opposite each mastoid process. In this same region should be soldered turned brass studs. These serve for its articulation with the next part of the apparatus. The axes of these studs should be in a line passing through the centres of the occipital condyles. The points of the mastoid processes are about in this line, and serve as valuable landmarks. In some heads this axis is not parallel to the transverse axis of the body, but greatly rotated to one side or the other. *If the studs are exactly on the axis of the condyles* the head can swing backward and forward with freedom, and yet the weight will be perfectly supported during all phases of the motion.

The necks of the studs fit into open bearings in the tops of vertical screws passing through the ends of a semicircle of iron rod which forms the next part of the apparatus. This arc of iron, marked *b* in the cut, presents at the centre of its length a short dependent stem which serves for its articulation with any suitable supporter made to rest either upon the shoulders or hips, according to the location and nature of the disease. By means of this latter articulation considerable lateral motion of the head is permitted. In some cases the lateral motion cannot be allowed; then the stem and the socket into which it fits can be cut square or triangular.

It is best to have a separable joint at this point, as it is often convenient for the patient to entirely remove the head supporter. The part *a* can be lifted out of its bearings and drawn forward. The opening at the back may be from two to three inches in width. The spring of the metal, and atrophy of the muscles of the neck, occurring in most patients, permits it to be quite narrow. After the removal of *a*, *b* can be lifted out of its socket.

This head supporter can be used with any spinal apparatus, a Taylor brace, a felt or plaster splint, or it can be attached to some suitable base improvised to meet the requirements of a particular case.

Its most novel feature is the articulation, which permits the free nodding motion of the head. This is a great convenience to the patient, and if the centres of the studs are accurately located could be permitted in every case except caries of the upper cervical vertebrae; perhaps in every case except where the occipito-atloid articulation was involved. The lateral motion is dependent upon the twisting of the cervical vertebrae about the axis of *b*, and can be employed when they are free from disease. It could perhaps be permitted in some cases of wry neck.

The apparatus has been used since 1878 in a case of Pott's disease located in the dorsal region, and has given good results. In cheapness and ease of construction it cannot compare with many forms of apparatus, particularly Sayre's jury-mast; but for patients who can afford it, and who require protracted treatment, it will be found a serviceable instrument. The minor details of construction vary with each case, and success depends largely upon the skill of the mechanic.

— Sir John Rose Cormack, Surgeon to the Hertford Hospital in Paris, is dead at the age of sixty-seven years.

## Reports of Societies.

### NEW YORK ACADEMY OF MEDICINE.

#### DISCUSSION ON BRIGHT'S DISEASE.

At a stated meeting of the Academy, held May 4th, Dr. J. G. ADAMS read an interesting memoir of the late Dr. James O. Pond, who died in February, 1881, at the advanced age of ninety. Dr. Pond was elected treasurer of the Academy in 1848, two years after the organization of the society, and served in that capacity for twenty-nine years, when the increasing infirmities of age compelled him to resign the position. At the conclusion of his paper Dr. Adams presented a portrait of Dr. Pond on behalf of his family, a number of whom were present on the occasion, and the president, Dr. Forlyce Barker, received it for the Academy with a brief eulogistic address.

The special order of the evening was then taken up, namely, an adjourned discussion on Bright's disease, suggested by a paper read before the Academy by Dr. T. A. McBride on the early diagnosis of this affection. The chair announced that the discussion would not be limited to the points treated of in Dr. McBride's paper, but would include the whole subject of Bright's disease, and then introduced Dr. William H. Draper as the first speaker.

DR. DRAPER, in opening, remarked that it was certainly a tribute to the genius of Bright, as well as a token of the slow progress which medical science makes, that the name Bright's disease was still retained to designate the various forms of renal disease. After alluding to the variety and importance of Bright's labors in this field, Dr. Draper said that he presumed that Dr. McBride in his paper referred exclusively to that insidious form in which there was but little, and possibly no, albumen in the urine and rarely any dropsy, and which was associated with granular contracted kidney and its correlated hypertrophied heart and atheromatous arteries. In the course of this affection he believed that diffused inflammation of the kidneys was liable to occur occasionally, and this, he thought, might perhaps explain the mixed symptoms which were observed in certain patients suffering from it. There was no doubt at the present day, however, of the essential entity of the granular kidney, with its insidious and often long-protracted clinical history.

In the discussion of this subject he thought it the utmost importance that the chief factors in the etiology of the disease should be carefully considered. The first of these he regarded as *heredity*, and the history of constitutional tendency in it, he said, was not less remarkable than that in glycosuria. Thus, Dickinson related one instance in which it occurred in three successive generations of a family. In connection with this point it was interesting to consider also the troubles belonging to the circulatory system which were so commonly met with in granular kidney. The next factor to demand attention in the etiology was the existence of the *gouty element*, whether hereditary or acquired, in regard to which there was now quite a general unanimity of the best authorities. The late Dr. Todd, in a lecture delivered in 1846, was the first to call attention to the atrophied kidney, and in the course of it he related the history of six cases of this form of disease associated with gouty diathesis. Some observers, however, regarded the kidney trouble as a coincidence rather than as the result of this diathesis, and

Dr. Draper then mentioned the opinions of Dickinson, Granger Stuart, Garraud, and other authorities in regard to the connection between the two. In considering this subject he believed that it was not enough to look merely at arthritic trouble as an evidence of the gouty diathesis, since he thought this was but one of its many manifestations in the system, and that it was beyond doubt a constitutional disease. The third factor was *senility*. The history of the affection showed that it was extremely rare under the age of twenty, and that it occurred most frequently between the ages of forty and sixty. Senility, however, was not due merely to age, but to the declining process in the system, and in some individuals, where it was induced by heredity or the wear and tear of life, the signs of premature old age were observed even in early youth. This seemed to prove conclusively that the granular condition of the kidney was only one part of a general process. In other words, the disease was not a local, but a general, one. The vascular changes, including hypertrophy of the heart, with or without valvular disease, he went on to say, did not escape the observation of Bright, and he then quoted from the latter to show his views concerning the correlation of vascular and renal disease. Bright, it was true, he continued, regarded the circulatory trouble as the result of the renal; but this opinion unquestionably led to the modern idea that they both have a common origin in a blood dyscrasia.

The claim made by Dr. McBride that there was a functional or formative stage of kidney disease, which might exist for many years before the full development of organic trouble, had been confirmed by many observers. The ordinary signs of the disease, as a rule, were not found until irretrievable damage had been done, and hence it was of great importance to recognize the evidences of the functional stage if possible. Among the latter Dr. McBride laid great stress upon pulse-tension; but it was not to be forgotten that this was liable to occur occasionally in functional trouble where the kidney was unaffected. Another point made by Dr. McBride was the existence of a high specific gravity in the urine, which was not affected by any measures employed to reduce it. This, however, was a very common symptom, due to a variety of causes, and he thought a greater number of cases were necessary to substantiate this sign. Its persistence, no doubt, constituted its chief value; but if it was persistent the questions arose, had not the disease already obtained a firm foot-hold, and was not this as indicative of organic trouble as persistent albuminuria? After all, Dr. Draper continued, was not the question of early diagnosis merely one of diagnosis of the conditions he had mentioned, — heredity, gout, and the atrophic changes of premature senility? These might, indeed, lead us to suspect the presence of formative cirrhotic kidney; but when there were persistent high specific gravity, cardiac hypertrophy, marked vascular tension, etc., was not the disease already formed?

DR. BARKER stated that twenty-two years ago there had been a long and interesting discussion on Bright's disease before the Academy, and that it was highly gratifying to note the great progress that had been made in pathological investigation since then. He could not but regret, however, that the therapeutics of the subject had not advanced in a commensurate degree. He hoped that this matter of therapeutics would not be neglected in the discussion which was to follow, as it was certainly a matter of great importance, and

in connection with it he would take the liberty of suggesting a point in regard to the therapeutic value of digitalis, and the discrimination of cases where it would be beneficial from those in which it was contra-indicated.

DR. ANDREW H. SMITH said in regard to the use of digitalis he believed that Fothergill was correct in his statement that it acted as a diuretic chiefly in those cases where it increased arterial tension. In regard to the general treatment of Bright's disease he said he had been much pleased with the results which he had obtained from the use of the milk diet. He also had faith in the value of oxygen (which promoted oxidation and diminished the quantity of uric acid), and always advised that his patients should be out in the air as much as possible. In this connection he would like to inquire if gouty subjects who took a good deal of outdoor exercise, like the English country gentlemen, were as liable to disease of the kidneys as those who led sedentary lives.

DR. S. O. VANDERPOEL alluded to a paper recently read before the Academy on Albuminuria in Adolescence (which had also been mentioned by Dr. Draper), in which the writer, Dr. Kinnicutt, claimed that this was due to three causes: (1) diminished arterial tension; (2) lithemic conditions; and (3) vaso-motor disturbances. In regard to the last two he said he was not convinced, because he had seen many cases of temporary albuminuria without the presence of either lithemia or vaso-motor paralysis. In regard to the first he had no doubt whatever, and he believed that a state of low arterial pressure, with more or less resulting venous stasis, always preceded the presence of albumen in the urine. He mentioned a variety of conditions in which he had noticed this, and then stated that it was hardly necessary to seek beyond the one cause, as it seemed to be so universally present. Dr. Vanderpoel went on to say that he heartily agreed with Dr. Draper in most of his conclusions, but he wished to protest against a misnomer which had already been far too long in use. What was known as red granular kidney was not at all a disease of the kidney, but was a strictly diathetic disease in which the whole system was implicated, and of which the interstitial changes in the kidney constituted only one factor. The atheromatous condition of the arteries he had generally supposed to precede the other signs, and he thought that the trouble in the heart began as early as that in the kidney. When there was found to be high arterial tension, he believed that the disease was present *de facto*, and it was a fact that patients rarely applied for treatment until they began to suffer from some of the secondary accidents of the affection, such as polyuria, epistaxis, or diarrhoea. This diathetic condition was most apt to occur in individuals of sedentary habits who indulged in high living or alcoholic stimulus; and the sooner the profession discarded the name of Bright's disease, in connection with the granular kidney, the better he believed it would be for medical science. As to the use of digitalis in this affection, he thought it was rarely applicable until the later stages, when the arterial tension had diminished and dilatation had supervened upon hypertrophy of the heart; for if it were employed while the tension continued high it would only do injury instead of being beneficial.

DR. KINNICUTT said that he did not mean to claim that the causes mentioned in his paper would cover all cases of temporary albuminuria, but that one or more of

them was found to be present in a certain number of the cases. In the affection under discussion this evening there were some cardinal points, such as polyuria, albuminuria, increased arterial tension, cardiac hypertrophy, certain changes in the *fundus oculi*, and the presence of hyaline casts in the urine, one or more of which he believed could be discovered in all cases. On this occasion he wished to call special attention to the significance of hyaline casts. It had been the tendency of many of the English writers, under the leadership of Dr. George Johnson, to underrate the importance of this pathological sign; but the best observers of the present day view the matter in a different light, and there was no doubt in his own mind that these casts represented a process of diminished intensity. Their presence, in connection especially with increased arterial tension, he thought, was of great significance, and was often perhaps an indication of that functional stage which was now so generally recognized. In many cases of lithemia he believed hyaline casts to exist, although they might be found only in small numbers. Polyuria, also, he considered a very early and important sign, and thought that enough attention was not generally paid to it by practitioners. As patients were rarely apt to speak of it themselves, careful inquiry was usually necessary to ascertain its existence; but, of course, the best method to determine the matter was to make daily measurements of the quantity of urine passed for a considerable period.

DR. BERRALL stated that out of two hundred records of urinary examinations in his possession he had found eighteen cases of albuminuria. Of these there was but one in which uric acid was noticed in the urine, although in two others he had found oxalate of lime, which was supposed to indicate an analogous condition. In three specimens the specific gravity was 1030 and over, in two 1008, and in three 1010. His impression was that albumen was by no means a frequent concomitant of lithemia or the presence of the urates. A *résumé* of one of his cases of chronic nephritis, he thought, might perhaps be of interest, as the records which he had of it extended from 1861 to 1879. The patient when first seen was a girl of ten years of age, and his attention was attracted to the kidneys from the fact that she suffered from occasional attacks of faintness. An examination of the urine revealed the presence of albumen and tube-casts, and she was at once put under a course of careful treatment. There were occasional exacerbations of the disease, but the result was on the whole very satisfactory. Thus, in 1871, there was no albumen; in 1874, a trace; in 1876 it had entirely disappeared, and in 1879 there was neither albumen nor casts. It was the general opinion that Bright's disease was always progressively fatal; but such a case as this seemed to suggest that there might be occasional exceptions to the rule. The treatment had consisted in carefully regulating the diet, and the use of hot-air baths, dry cups and iron, the latter usually in the form of the tincture of the muriate or the liquor ferri subsulphatis. Functional nervous disturbances, he said in conclusion, should always attract attention to the kidneys.

DR. MCBRIDE thought that the point of greatest importance in the discussion was to ascertain whether we could really establish a stage of early occurrence in Bright's disease characterized by a sufficient number of symptoms to allow of its detection. Hitherto a low specific gravity, an increased quantity of urine,

and the presence of certain tube-casts, had been necessary to diagnosticate the disease; but if it could be said that before the time when these evidences occurred there was a constant set of symptoms which might appear for years before the signs which indicated the closing period of the malady, he believed it to be a very important point gained. These he thought could now be detected, although the most careful observation was often necessary to establish their presence. Thus it was really a very difficult matter to determine an increased pulse-tension with accuracy, and the great majority of the urinometers in use were very imperfect. Again, if the quantity of albumen was very minute, it was very hard to detect; but in this connection he could not too strongly recommend the method of Dr. Munn for determining albumen. Nor was it always easy to make out hypertrophy of the heart. If from these points, however, we could succeed in recognizing an early stage of Bright's disease, he thought we had accomplished a great deal. The earlier it could be detected the more important, of course, would be the bearing of therapeutics on the case. It was to Dr. Draper, he believed, that the profession was indebted for the best dietetic plan of treatment for those suffering from sub-oxidation (one which was widely at variance with that commonly laid down, and especially by the English authorities), and he hoped that the doctor would favor the Academy with a synopsis of his views on the subject.

DR. DRAPER said that he did not wish to claim any originality in this connection, but that it was as if a sort of prophetic vision had been revealed to him when, several years ago, he got hold of a book that was one of the most remarkable ever written, and was far ahead of both the pathology and therapeutics of the times. This was the work of Dr. Bence Jones on Pathology and Therapeutics, which appeared in 1860, and was devoted to a discussion of affections which the author designated as the diseases of sub-oxidation. It was in the main an elaboration of some of Liebig's views, and treated chiefly of the allied disorders of glycosuria and gout. This strictly chemical view of disease had been very severely criticised by many authorities, but he had no doubt of its correctness, and that it would be ultimately recognized by all. Dr. Draper then said that the subject was too vast to admit of being treated of properly in a few minutes; but that with the president's permission he would be very glad to prepare a paper upon it to present at some future meeting of the Academy. In reply to Dr. Smith's question whether contracted kidney was not more common among gouty persons of sedentary habits than those who lived for the most part out-of-doors, he was not able to give a definite answer, but his impression was that such was not the case. In each individual there seemed to be some inherent vulnerable part which was the first to be affected by disease, and on the vulnerability of particular tissues or regions, such as the skin, the mucous membranes, the joints, and the arterial system, depended the seat of the gouty attack. After some remarks on the use of digitalis, Dr. Draper stated that he had found morphia a much more valuable remedy in the later stages of granular kidney, whether there was a valvular complication of the heart or not. It was well known that at this period dyspnea was apt to be one of the most distressing symptoms, often causing the most agonizing suffering; though why this should be the case had never been satisfactorily ex-

plained, since it was liable to occur whether there were any valvular trouble or not. In this condition digitalis did not afford any relief; but morphia was of the greatest possible benefit.

## PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

MAY 8, 1882. DR. J. C. WARREN presided.

### PNEUMONIA IN CHILDREN.

DR. FIFIELD spoke of the various forms of pneumonia which occur in children, especially of that variety which appears at times to be infectious, and also that class of cases which, beginning with the symptoms of a pleuritis, and in its course having a pulse of perhaps 110 and a temperature of 102° or 103° F., continues much longer than is usual in an ordinary pneumonitis and often involves both lungs. As an instance of the latter class, Dr. Fifield reported the case of a boy seven years old, who was previously well and strong and was out on the day when he was attacked; in the afternoon, while playing with another boy, he was thrown down, and in the evening complained of pain in the left side of his chest. Dr. Cushing, of Dorchester, was called to the case, diagnosticated acute pleuritis, and applied leeches and a poultice. A few days later Dr. Fifield saw the patient, and found that he had a pulse of 110 and a temperature of 103° F.; the symptoms at this time pointed towards a pleuritis, and Dr. Fifield concurred with Dr. Cushing in the diagnosis of that disease. A week later such urgent dyspnea appeared that Dr. Fifield strongly recommended thoracentesis, but was not allowed to perform it. On the following day bronchial respiration and râles were found in the chest, and the dullness, which at first was only on the left side of the chest, was now found on both sides, front and back, with the exception of an area of resonance over both apices in front, where the respiration was good. These symptoms continued for another week, the lungs assuming an apparently wooden condition, and respiration being absent over both backs. May 6th Dr. Rotch was summoned in consultation, when the following condition of affairs was found: The child was suffering from orthopnea; face and hands somewhat livid; pulse 120; respiration 50; temperature in the morning 102° F. The vocal fremitus was not marked; the heart's apex was in position; percussion showed complete dullness over both lungs, front, side, and back, excepting moderate dullness above the spine of the right scapula, and fairly good resonance under both clavicles in front as low as the third ribs. On auscultation faint respiration was heard throughout both lungs, with numerous subcrepitant râles and bronchial respiration at the apex of the left scapula, with harsh, exaggerated, vesicular respiration under both clavicles corresponding to the areas of resonance. The vocal resonance was slightly increased. Dr. Rotch agreed with Dr. Fifield that the case was one of fibrinous pneumonia, that resolution was just beginning, and that the treatment, which was chiefly stimulating, should be continued. The child died from exhaustion, on the morning of May 8th. No autopsy could be obtained. The duration of the case was about three weeks.

Dr. Fifield remarked upon the prolonged duration of the attack and the unusual lowness of the temperature, and said that cases of this kind showed such a difference from the common pneumonia of the adult that much remained to be written on this subject in children.

Dr. C. P. PUTNAM said that he recalled two cases seen by him in consultation where the duration of the disease was unusual; the first was a boy eight years of age, who was seen by him at the end of the third week of what he supposed to be a lobar pneumonia; in this case catarrhal symptoms developed later, and the child has probably died. The second case, also a child, after lasting for some time, began to resolve, but complete resolution never took place, and this case probably also died. Dr. Putnam was inclined to think that the prognosis in these prolonged cases was unfavorable.

Dr. ROTCH said that in the few cases which he had had an opportunity of observing of prolonged duration in the fibrinous pneumonia of children the prognosis had not been especially unfavorable, and that he had found a great variety in the course of the disease as to temperature, pulse, and duration, without a necessarily fatal termination; he especially recalled the case of a little girl, six years of age, who was attacked with a fibrinous pneumonia involving the whole of the right lung, in whom the temperature was never especially high, perhaps  $102^{\circ}$  or  $103^{\circ}$  F. During the stage of hepatization, which came after the usual initiatory symptoms, complete dullness with absence of râles took place, and this state of affairs continued for three weeks, so that Dr. Calvin Ellis, to whom the case was described, was so convinced that it must be a case of pleuritic effusion that he took his aspirator with him when he went to examine the case with Dr. Rotch, fully expecting to tap; but after careful examination he agreed that it was a case of lobar pneumonia, and this view was corroborated a few days later by the appearance of resolution as shown by numerous subcrepitant râles and returning resonance. The child was much debilitated, and during her convalescence had an attack of acute pemphigus confined to the chest, but she recovered entirely, and two years later an examination showed the lungs to be normal, and the child strong and well. Dr. Rotch also called attention to the fact that where a large portion of the lung is involved we often have a lower temperature, and less severe constitutional symptoms, such as delirium and stupor, than where a small area, especially at one of the apices, is attacked.

Dr. SABINE spoke of a case occurring in his practice, where a child of four years was attacked with a fibrinous pneumonia of the lower lobe, which ran its course, and resolved in three days. Immediately after recovery, however, the upper lobe was attacked with apparently the same process, and remained consolidated for three months, finally clearing up, and the child recovering its health, and remaining well ever since.

Dr. FIFIELD spoke of the rapid changes which at times take place in the physical signs of children's pneumonia, sometimes a little dullness in one place changing to another area on, perhaps, the next day, and patches of râles found here and there.

Dr. ROTCH suggested that as these were usually the physical signs of the catarrhal form of pneumonia, that possibly the instances where Dr. Fifield had observed

this state of affairs were cases of acute catarrhal pneumonia.

Dr. WEBBER exhibited

SPECIMENS OF INTUSSUSCEPTION OF THE INTESTINES AND TUMORS OF THE BRAIN,

a description of which will appear in full later.

Dr. J. C. WARREN read a paper on

EXCISION OF THE WRIST-JOINT,

which will be published in full. He stated that this operation had not been popular with surgeons on account of the great deformity and impaired usefulness of hand which resulted from it. Lister's complicated method had been supposed to overcome the difficulties which led to this condition. In a diseased wrist the anatomical landmarks given by Lister could not be easily followed, and he had found that an external and internal lateral incision, both of which were in a line slightly posterior to that of the vessels, caused very little mutilation of the soft parts concerned in the movements of the hand. He had performed the operation seven times. It consisted in removing the entire joint, through the incisions mentioned, under antiseptic precautions. One case was traumatic, the others were cases of caries. In one case only was amputation necessary. In most of them there was good motion of the joint, but the metacarpophalangeal articulations were stiff, owing to the shortness of the metacarpal bones. The after-treatment was tedious, but a tolerably straight and moderately useful hand was obtained. Most of the cases had been watched for several years after the operation.

## Recent Literature.

*Sensation and Pain.* By CHARLES FAYETTE TAYLOR, M. D. New York: G. P. Putnam's Sons. 1881.

This is the title of a brochure reprinted, we believe, from the *Popular Science Monthly*. It is for the general public rather than for medical readers, and contains some information which it is important all people should be familiar with. The purport of the writer is to call attention to the influence of the emotions, and the errors which honest persons may fall into by reason of the fallacies of their sensations. An interesting incident is related illustrating this point. A soldier, during the battle of Williamsburg, was met inquiring the way to his regiment, from which he had been separated. The officer to whom he spoke gave him the information, and advised him also to have his arm dressed. The private denied that anything was the matter with his arm, and it was only on ocular demonstration that he could be convinced that his hand had been entirely shot away.

The following case of medical interest is mentioned: A gentleman who had suffered from "dislocation" of the hip-joint since childhood considered himself cured by the Italian bone-setter Regina dal Cin, who claimed to have pulled the limb into a normal position. On examination by Dr. Taylor, an ankylosis of the femur at right angles with the pelvis was found. The relief which had been apparently gained was simply that the patient, formerly accustomed to use a high shoe, had been unconsciously taught to tilt his pelvis and bring his affected limb into what was supposed to be the axis of the body.

# Medical and Surgical Journal.

THURSDAY, MAY 18, 1882.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year including postage.*

*All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.* HOUGHTON, MIFFLIN AND COMPANY,  
No. 4 PARK STREET, BOSTON, MASS.

## THE NEW UNITED STATES PHARMACOPEIA.

We are pleased to learn that the manuscript of the sixth revision of the United States Pharmacopœia is now in the hands of the printer, and that the book will appear next August. Hitherto our medical profession have hardly known in what the Pharmacopœia consists, and have generally gone to the Dispensatories for information in regard to the composition of official as well as unofficial medicinal preparations. We call to mind that the first effort towards the preparation of an official work originated in Boston, and resulted later in a plan which was instituted in answers to circulars issued by the New York State Medical Society, and approved by many other State medical societies and medical colleges. At first the various societies and colleges were divided into district conventions who afterwards sent delegates to the General Convention held in Washington, on the 1st of January, 1820. At this General Convention the works of the district conventions were consolidated into one work, adopted, and ordered to be published by a committee appointed for that purpose; also the general plan for providing for a second National Convention was then instituted, and has upon subsequent meetings been extended to the succeeding decades. The publication committee of the first edition of the Pharmacopœia of the United States of America (1820) consisted of five members, of the fourth and fifth revisions of nine and fifteen members, respectively, and of the present or sixth revision of twenty-five members.

The copyright of the first edition was sold to a Boston publishing house "for a large sum," and this copyright apparently was held by the publishers in high esteem, if we can give any credence to the notification which occurs upon the reverse side of the title-page of that work. The fifth edition, according to the report at the last convention, was sold for \$168.42, an agreement having been previously made with Messrs. Lippincott & Co. by which this firm agreed to give the committee of revision twenty-five copies free of charge, and to pay the expenses of the committee provided these did not exceed \$300. As the official reports of other committees did not present the details of financial matters, we have no means of ascertaining what money was paid for the copyright in any other years. The present or sixth edition has been assigned by contract to Messrs. Wm. Wood & Co., who are allowed to use the manuscript only in the manner prescribed by this contract, and hence neither they nor

any other publisher can use the material thus collected in any other book. We may surmise that this edition will be of great value to the professions of medicine and pharmacy, inasmuch as \$4,400 is guaranteed on the first year's sale of the book. We anticipated that it will occupy the place that has heretofore been held by the various Dispensatories, but regret to learn that no list of doses is to be included among its pages.

We are informed that the largest and most useful contributions in this book are from the laboratory and pen of Prof. A. B. Prescott, of Michigan, and that it will contain an admirable description of chemical pharmacy to which Prof. H. B. Parsons and E. S. Wood have lent valuable assistance. Mr. Taylor, of Philadelphia, has, we also learn, rendered material assistance in the preparation of the text. Among other contributors we are permitted to state in their several order, Professor Diehl, of St. Louis, on Fluid Extracts, the process for preparing which promises to replace those which are at present unreliable and of uncertain medicinal value; Professor Maisch, of Philadelphia, on Pharmacognosy; Dohme, of Baltimore, on iron preparations; Professor Remington, of Philadelphia, on some laboratory work of whose nature we have not been fortunate enough to learn; Professor Scheffer, and Professor Wall, of St. Louis, the latter upon certain stable syrups; Professor Oldberg, Mr. Thompson, of Washington, and Professor Bedford, of New York.

Dr. Charles Rice, of New York, the chairman, has skillfully organized his committee, and has devoted more time, and given more useful service, than any of his colleagues, and has, we understand, well repaid the expectation which led the convention to place him at the head of the work.

Though we do not wish to disparage the work of the committee of revision of former years, yet that they did not successfully accomplish their work would seem to be shown by the success with which private Dispensatories have hitherto supplanted in a great measure the Pharmacopœia, notwithstanding the high price commanded by the first-named books and the low price asked for the Pharmacopœia. There seems to have been considerable excitement among certain publishers of medical books over a supposed partiality on the part of the committee in awarding the contract for publication of the Pharmacopœia. The award was made to a New York publishing house which is untrammelled by books of a character likely to compete with the National Pharmacopœia. The criticisms of the committee's action, which have been sufficiently warm, have proceeded mainly from Philadelphia, and found expression in two medical journals, both of which are owned by publishers already interested in private Dispensatories. We refrain from further editorial criticisms and exposition of the subject of publishers' quarrels, as we do not suppose our professional readers are as much interested in these matters as in the main question of having a truly national and good practical Pharmacopœia, of the scope of which we have given an outline, and upon the value of which we shall in due time present our views, that is, after the book has issued from the press.

## THE DEATH-RATE OF NEW YORK.

THE official figures of the Bureau of Vital Statistics show a decided increase in the death-rate of New York city during the past year or two. Thus, in 1879, the deaths per thousand of the estimated population were 25.82; in 1880, 26.47; and in 1881, 30.97. During this period there has been no extensive and fatal epidemic to account for the increased mortality, and, consequently, inquiry has naturally been directed to the explanation of this increase, and the consideration of the question why New York should be less healthful than many other large cities. On careful investigation, however, the facts of the case seem to show that the increase in the death-rate is an apparent rather than a real one, and that the mortality of the city, although, unfortunately, much greater than it ought to be,—principally owing to the prevalent ignorance and lack of sanitary precautions among its immense tenement-house population,—is in reality by no means alarming.

One of the explanations of the apparently high rate of mortality is found in the fact that the population of the city is really greater than that estimated in the tables used in making up the statistics. Thus the census taken in June, 1880, which showed the population to be 1,206,577, could not have been accurate, since a large number of the regular residents are always absent from the city at that time of the year; and the estimated population of 1881, 1,212,533, is considered by the best judges to be short of the actual figure. The immense number of buildings—especially apartment-houses—which are annually being erected, and the fact that they are all occupied as soon as completed, affords some evidence of the great rapidity with which the population is constantly increasing. There are, however, additional reasons why the mortality of New York should appear disproportionately great. In comparing it with that of other cities, it should be borne in mind that in many places the still-births are not, as in New York, included among the deaths. During the past year no less than 2,462 of these are reported. In many places, too, the hospitals are outside the city limits, and the deaths occurring in them are not included in the mortality lists, although the greater number of patients may be brought from the city. Then there is a very large and continually increasing emigrant population passing through the city of New York, and as almost all the sick and weakly remain there, many of the latter die, and are, of course, credited to the city death-rate. Again, a large number of serious or incurable cases which baffle the skill of country practitioners are naturally sent to the metropolis for treatment, and many of these die while in the city. Still another reason for the apparent high death-rate is that the returns of deaths are complete, so that no decease escapes registration; which is not the case in many other cities. In New York the statistics of physicians or undertakers are not relied upon; but the law which requires that a body cannot be buried or removed until a death certificate has been filed at the office of the Board of Health is unvaryingly enforced by the police. In

this connection it may be well to mention, incidentally, that one reason why the number of deaths is apparently so much greater than that of the births in New York is, that while every death is necessarily registered, it is found impossible to strictly enforce the law requiring all births to be reported, and, consequently, a considerable number of these escape the attention of the Bureau of Statistics.

It has been found that the simplest method of determining whether an increase in the death-rate is due to an absolutely greater mortality, or only to one relatively greater, owing to an increase of population not recognized in fixing the rate, is to compare the deaths of young children in any year with those in preceding years; and with reference to this point, Professor Chandler, President of the New York Board of Health, has had prepared the following statistical table, which goes back to the organization of the board.

| Years. | Population. | Total Deaths. | Over Five Years. | Under Five Years. | Percentage.      |                   |
|--------|-------------|---------------|------------------|-------------------|------------------|-------------------|
|        |             |               |                  |                   | Over Five Years. | Under Five Years. |
| 1867   | 899,092     | 23,264        | 19,596           | 12,274            | 47.00            | 53.00             |
| 1868   | 913,298     | 24,706        | 11,668           | 13,067            | 47.50            | 52.50             |
| 1869   | 927,728     | 25,167        | 12,398           | 12,859            | 48.91            | 51.09             |
| 1870   | 942,292     | 25,174        | 15,741           | 13,533            | 50.49            | 49.51             |
| 1871   | 954,095     | 25,976        | 14,065           | 12,971            | 51.92            | 48.08             |
| 1872   | 967,142     | 32,423        | 16,235           | 16,188            | 50.42            | 49.58             |
| 1873   | 979,411     | 39,027        | 18,833           | 14,182            | 51.24            | 48.76             |
| 1874   | 992,646     | 38,539        | 14,533           | 13,956            | 51.19            | 48.81             |
| 1875   | 1,011,880   | 39,623        | 15,574           | 14,839            | 51.72            | 48.28             |
| 1876   | 1,035,535   | 39,152        | 14,942           | 14,210            | 51.26            | 48.74             |
| 1877   | 1,059,362   | 26,293        | 13,896           | 12,397            | 53.03            | 46.97             |
| 1878   | 1,083,571   | 25,008        | 14,598           | 12,410            | 54.05            | 45.95             |
| 1879   | 1,097,593   | 28,542        | 15,595           | 12,777            | 54.92            | 45.08             |
| 1880   | 1,206,577   | 31,937        | 17,287           | 14,650            | 54.13            | 45.87             |
| 1881   | 1,212,533   | 38,624        | 20,887           | 17,737            | 54.08            | 45.92             |

These figures, showing that there has been a gradual diminution in the number of deaths of those under five years of age from fifty-three per cent. to less than forty-six per cent. during the past fifteen years, indicate a decided improvement in the public health, although the death-rate in this class of the population is still excessive. Had the proportion been as large in 1881 as it was in 1867, there would have been 23,553 deaths instead of 17,737.

As evidence that the population of New York has increased to a greater extent than is shown by the estimates used in making up the returns of the Board of Health, in addition to the statistics furnished by the building departments, may be mentioned the circumstance that the elevated railways carried about fifteen per cent. more passengers and the street-cars about ten per cent. more passengers in 1881 than in 1880. Other indications of the same fact are afforded by the returns of still-births, which show an increase of over 12.20 per cent. between 1879 and 1881, and by the number of deaths from causes which are but slightly, if at all, dependent upon unsanitary conditions. Take, for instance, the deaths from apoplexy, cancer, and suicide, as shown by the following table, lately published in one of the New York papers:—

| Cause of death. | Number of Deaths. |      |      | Per cent.<br>increase<br>1880<br>over<br>1879. | Per cent.<br>increase<br>1881<br>over<br>1880. | Per cent.<br>increase<br>1881<br>over<br>1879. |
|-----------------|-------------------|------|------|--|--|--|
|                 | 1879              | 1880 | 1881 |  |  |  |
| Apoplexy . . .  | 489               | 516  | 587  | 5.52   | 13.76  | 20.04  |
| Cancer . . . .  | 572               | 659  | 704  | 15.20  | 6.82   | 23.07  |
| Suicide . . . . | 117               | 152  | 166  | 29.88  | 9.21   | 41.88  |

An indication of the great increase in the floating or transient population of the city is seen in the fact that in 1881 there were 318 deaths of persons whose residence was out of New York, while in 1880 there were 261, and in 1879 only 147, showing an increase of 21.84 per cent. since the latter year.

#### THE PETITION FOR A STAY OF PROCEEDINGS IN THE CASE OF GUTEAU.

SOON after the assassination of President Garfield we expressed the opinion, to which we still adhere, that the deed was the act of an insane man, much less insane, however, than the available evidence seemed to make him at that time. There were two methods open to the government in the conduct of his trial. The first, and to our thinking the best, would have been to have had Guiteau examined, as is the custom in Germany and France, by a commission of experts, upon whose statement as to his medical insanity the court should decide, as is also the law in France and Germany, whether or not to proceed with a trial; and in those countries, as a matter of fact, a criminal is sometimes convicted and sentenced in spite of the commission's unanimous decision of medical insanity, which may be altogether different from legal insanity or irresponsibility. The second course, the more common one in England, was adopted, the assassin was given a long trial, an immense mass of expert and other testimony was brought by the government, including a number of witnesses summoned for the defense, to show that Guiteau was at least legally sane, and he has been sentenced to death. If Guiteau could have been pronounced insane and secluded for life without trial, there could have been to our mind no better solution of the case, for the scenes of those disgraceful three months of his exhibition in Washington have furnished to the criminally inclined an education which must result sadly to society. There was the same disagreement in opinion, however, among the experts who saw Guiteau before the trial as was shown on the witness stand. One thought him sane; another considered that he had the insane temperament; a third regarded him insane but thought that there would be a wide difference in opinion as to his responsibility.

We do not purpose discussing, at present, the points of law involved in this case, nor shall we criticise the testimony and conduct of the trial now. It is simply with reference to the practical question of staying the execution, for which a petition is in circulation,

that we wish to present a few considerations to those who are in doubt as to their action in the matter. In the first place, by the highest authority, the responsibility of such criminals as Guiteau is far from being agreed upon even by experts.<sup>1</sup>

Further, society makes the laws, and has a pretty clear idea of what kind of persons it wishes to hold amenable to punishment, and the evidence of what it calls accountability was so overwhelmingly brought out during the protracted trial that, in the opinion of one of the most learned and distinguished judges of our State, who was present during the assassin's testimony on the stand, the jury would have agreed upon a conviction if every doctor in the court room had sworn to the insanity of the prisoner. The senior physician present, long recognized as a man of the highest personal character, and an authority in insanity, one of the Society of Friends, who do not approve in general of hanging, reluctantly came to the conclusion that Guiteau should be hanged if any one should be; and if only three experts, accomplished men, although without large practical experience in insanity, were called upon by the defense to give their opinions as to Guiteau's mental state, it was because the expressed opinion of the others was either favorable to the prosecution or not strongly favorable to the defense. Many of these facts we are compelled to acknowledge in fairness, although they conflict with our own views to a great extent.

Now that the trial is over, the whole question of pardon or withholding the execution of the law is one of the protection of society. The assassin has little claim upon the interest or sympathy of the community. Before sentence the prisoner should have the benefit of the doubt to a much greater extent than Guiteau has had it. As the matter now stands, society should have the benefit of any doubt, and we hold, with all due deference to those who think otherwise, that life would be rendered less safe if the President's hand should reverse the verdict in this case. Much as we regret to see hanged, even for a murder in which the motive and method were those of the criminal, a man whom we consider insane, and strongly as we are of the opinion that seclusion for life without trial would have been the proper disposition to make of Guiteau, we see that our opinion has not prevailed, and we fail to find any sufficient reason for asking the executive interference to save him from the gallows. The commission of experts asked for in the petition would be certain to disagree, just as there was a disagreement among the experts twice before, the inevitable result would be an opinion no more favorable to Guiteau than those which have been already given, and we should only get a continuation of the doctors' wrangle neither creditable to the medical profession nor beneficial to society. If the court in full bench

<sup>1</sup> Kraft Ebing says, in the last edition of his book, "Die Frage nach der rechtlichen Verantwortlichkeit solcher degenerativer Individuen muss beim gegenwärtigen Standpunkt der Strafgesetzgebung als eine offene bezeichnet werden. Möge sie vom Juristen generell und in konkreten Fall gelöst werden! Der Gerichtsarzt hat seine Aufgabe gelöst, wenn er in gegebenen Fall die organische Grundlage der scheinbar rein ethischen Depravation nachgewiesen, ihren Umfang feststellt, und das Zwangsmässige des scheinbar willkürlichen Gebahrens solcher Individuen dargelegt hat."

should fail to sustain Judge Cox's decisions, it will be time enough then to discuss the question from the point of view of another trial.

### MEDICAL NOTES.

—We have received a request to obtain medical signatures to a petition to the President of the United States asking in the name of psychological science for a stay of execution in the case of Charles J. Guiteau, and forward the same to Dr. Geo. M. Beard, of New York.

The petition is based on the following "facts":—

First. For more than twenty years Guiteau has been hopelessly insane. Secondly. Under a right management of the case the opinions of our leading authorities could have been formally brought before the court, and would have radically changed the character and probably also the issue of the trial. Third. The instincts and the customs of all civilized nations are opposed to the hanging of the insane. Years since, the insanity of Guiteau was recognized by some of his relatives, and formal efforts were made to send him to an asylum as an incurable and dangerous lunatic. One medical certificate (that of the family physician) was ready, and, but for a complication of accidents, the other would have been obtained. During these twenty years no asylum in the world would have refused admission to Guiteau, and in all probability none would have discharged him. The insane out of asylums as well as in asylums are entitled to the protection of that law which declares that no lunatic can commit a crime.

"If this petition for a stay of proceedings should be granted, we would further petition for the appointment of a commission composed of our best recognized authorities who did not testify at the trial, to examine into the mental condition of Guiteau, and report thereon."

"In Germany and in France—countries which have led the world in the scientific study of insanity—it has long been the custom to appoint such committees of experts in cases where the plea of insanity has been entered, and receive their reports *before* the trial. If this course had been pursued in the case of Guiteau, this country would have been spared the humiliation and disgrace of a protracted trial of a lunatic."

—We are requested to remind intending competitors for the Middlemore prize in ophthalmology, that all essays must be forwarded by the 31st May next, under cover, with a sealed envelope bearing the motto of the essay, and containing the name and address of the author, addressed to the General Secretary of the British Medical Association, 161A, Strand, London. The amount of the prize is £50, and the subject of the essay is The Scientific and Practical Value of Improvements in Ophthalmological Medicine and Surgery made or published in the past three years.

—The Secretary of the Surgical Section of the American Medical Association has the following progress to report in regard to papers for the next meet-

ing: Prof. A. C. Post, Lupus Exedens of Face; Dr. J. R. Weist, Elastic Tension in the Management of Cases of Delayed Separation of Ligature; Dr. Henry A. Martin, Advances in Conservative Surgery of the Joints; Dr. Carl Seiler, Some Remarks upon Electricity in Surgery; W. M. Fuqua, Subperitoneal Surgery; Dr. A. Van Derveer, Cleft of Hard Palate; Dr. Oscar J. Coskery, Modification of Plaster Splints; Dr. G. W. Nesbitt, Ununited Fracture of Femur treated by Exercise; Dr. John E. Link, Alcohol as an Anesthetic; Dr. Wm. Hill, Laparotomy; Dr. Ephraim Cutter, Bi-Fracture of Patella, Partial Bony Union after Eight Years; Dr. Wm. Stewart, Fracture of Elbow Joint. Drs. J. H. Dara, Joseph H. Warren, Henry O. Marcy, Edward Borek, and B. H. Riggs promise papers, titles not received. The secretary, owing to the death of the chairman, will read a paper on Excision of Portions of the Alimentary Canal covered with Peritoneum, as the address on Surgery. Gentlemen wishing to read papers will please notify the Secretary of the Section, William A. Byrd, M. D., 407 Jersey Street, Quincy, Illinois.

—At the annual meeting of the Norfolk District Medical Society, held on the 9th inst., the following officers were elected for 1882: President, James Morrison, M. D.; Vice-President, J. Y. Streeter, M. D.; Secretary, Librarian, and Reporter, George D. Townsend, M. D.; Treasurer, Edward G. Morse, M. D.; Commissioner of Trials, Joseph Stedman, M. D.; Censors, W. H. Campbell, M. D.; G. W. Clement, M. D.; E. L. Farr, M. D.; G. K. Sabine, M. D.; E. T. Williams, M. D.; Councilors, G. A. Bragdon, M. D.; Benjamin Cushing, M. D.; C. C. Hayes, M. D.; J. S. Flint, M. D.; R. T. Edes, M. D.; James S. Greene, M. D.; H. G. Morse, M. D.; U. O. B. Wingate, M. D.; J. A. Winkle, M. D.; Henry P. Bowditch, M. D.; Gustavus P. Pratt, M. D.; Robert Amory, M. D.; Joel Seaverns, M. D.; Edward Mead, M. D.; David B. Van Slyck, M. D.; Nominating Councilor, J. S. Flint, M. D.

—According to *New Remedies* the Minister of the Interior of Russia has notified the fourteen Jewish proprietors of pharmacies in St. Petersburg that they will no longer be permitted to pursue their calling, and has required them to dispose of their business within a year to pharmacists who are not Jews. Jewish assistants are required to resign their situations and cease the practice of pharmacy at once.

### NEW YORK.

—The pall-bearers at the funeral of the late Dr. James R. Wood were Drs. Alonzo Clark, Austin Flint, Sr., T. Gaillard Thomas, John T. Metcalfe, Willard Parker, Isaac E. Taylor, Lewis A. Sayre, Alfred C. Post, Fordyce Barker, Thomas F. Cook, F. S. Dennis, and Charles R. Shippard; and a eulogy was delivered by the Rev. Dr. Robert Collyer. The Commissioners of Charities and Correction, who were also present, ordered that the flags on all the hospitals and other public institutions under their charge should be displayed at half-mast on the day of the funeral.

—The annual reception of the ladies' association

having the care of the House of Rest for Consumptives was held at the institution at Tremont, New York, on the 2d of May. The present accommodations are for only forty inmates, but the erection of buildings at a cost of \$80,000, in which one hundred and fifty patients can be cared for, is in contemplation.

— At a fair just closed, at Irving Hall, about \$35,000 has been raised for the hospital of the French Benevolent Society of New York.

— President Chandler, of the City Board of Health, is engaged in preparing an exhaustive report on the milk supply of New York and its regulation, to be sent to the State Board of Health, and to be used for the purpose of securing still needed legislation against the adulteration of milk.

### Miscellany.

#### A CONFERENCE OF SANITARIANS IN REGARD TO MALARIA.

DR. ELISHA HARRIS, Secretary of the New York State Board of Health, Professor Lindsley of the Connecticut Board of Health, Dr. Chamberlain, its Secretary, and Dr. John S. Billings of the National Board, were in Boston last week to confer with Dr. C. F. Folsom of the National Board, and Dr. H. P. Walcott, Secretary of the Health Department of the Massachusetts Board of Health, Lunacy, and Charity, in regard to the continued development of malarial disease in New York and New England.

The National Board of Health is engaged in an investigation, having for its object the proof of the reliability of Klebs and Condelli's results in regard to the character of the malarial poison. In this, willing assistance is promised by the sanitary officers present at the late conference. A circular will shortly appear asking for the coöperation of individual physicians.

#### JOHN T. HODGEN, M. D.

DR. JOHN T. HODGEN, Professor of Anatomy in the St. Louis Medical College, died at St. Louis, April 28th, in the fifty-seventh year of his age. He was born in 1826 in La Rue County, Kentucky, and was the son of Rev. S. P. Hodgen, a minister of the Campbellite Church. He graduated at Bethany College, Virginia, and subsequently took a medical degree in St. Louis, where he lived for thirty-five years. He was for the greater part of this time a professor in the St. Louis Medical College, of which he was Dean at the time of his death.

He was very successful as a general practitioner, but was best known as a surgeon. In surgery his reputation at the West was very extensive. His modification of Smith's anterior splint, known by his name, and his views on the treatment of fractures have increased the number of those familiar with his name. He was President of the American Medical Association, in 1881, and presided at its last meeting in Richmond.

He was taken sick in the court-room whilst attending a trial as a witness, and reached home with difficulty in great pain. His death, as shown by an au-

topsy, resulted from peritonitis consequent upon a rupture of the gall-bladder.

He had suffered for a number of years from attacks of bilious colic.

#### BISMUTH AND TIN IN AUSTRALIA.

DR. J. R. M. ROBERTSON, who recently returned from Australia, read a paper on "Bismuth and Tin in Australia," before the Geological Society of Glasgow. He reports the discovery of very considerable deposits of metal in the northern portions of New South Wales.

Dr. Robertson described carefully the geological features of the place where the bismuth is found, and the various forms in which it occurs: (1.) Native metal in irregular bunches or nests throughout the substance of the quartz, the masses weighing from one half pound to fifty pounds; (2.) As oxide forming thirty to fifty per cent. of the soft casing of the quartz veins; (3.) In characteristic leaden-gray acicular crystals of sulphuret, though in smaller quantities.

"In nearly all the lodes large quantities of molybdenite occur; indeed, this mineral seems always to accompany the bismuth. At present it is thrown aside as worthless."

The ore is said to be of such great purity that a charge of £15 per ton will amply repay the smelter for his trouble. The doctor goes on to say that all the other known mines yielding bismuth (in Saxony, Bolivia, Mexico, Cornwall, and South Australia) are controlled by the "London Bismuth Ring," who reap enormous profits, the price being kept so high as to restrict the total consumption of the world to seventy tons per year, the chief use being for the production of bismuth subnitrate, much used as a cosmetic and as a medicine for treatment of gastric disorders; a minor use for bismuth is in production of type metals and fusible alloys.

It remains to be seen whether the price of this useful metal will be materially affected by this recently announced discovery. In this country the price of metallic bismuth ranges at present not far from \$1.90 to \$2 per pound, the subnitrate being sold at about the same price, and the subcarbonate at a slight advance. — *Sanitary Engineer.*

#### CHARCOAL FILTERS.

A CORRESPONDENT of the Washington *Evening Star* calls attention to a misunderstanding of the proper use of charcoal. Being porous and entirely insoluble in water, it makes a good filter, but "if," says the correspondent, "you have a noxious and offensive fluid which it is your wish to dispose of as speedily as possible, retaining none of the odor in your house or apartment, it is obviously unphilosophical to pour this fluid over a quantity of charcoal exposed in an open vessel, at the bottom of which may be a grating and waste pipe, to allow the fluid to pass off. By this means you simply filter out of the fluid, which it is your object to get rid of as speedily as possible, a large part of its offensive matter, which is retained in the charcoal to be given out in the atmosphere of your room or building. You send away the bad fluid purified of a portion of its bad-smelling substance, which remains behind in the charcoal to offend your olfactories and

poison your air. This, therefore, is obviously an improper use of charcoal. The surfaces of the drain hopper, where fluids of this character are thrown, if smooth porcelain or metal, require only thorough cleansing with water. The smell, which will still proceed from such contrivances, then, must be attributed to the matter that remains upon the inner surfaces of the openings, gratings, and waste pipes which cannot be reached by the brush, and the only effectual remedy for this is an occasional application of a solution of muriatic acid, which will loosen the matter and cleanse

these inner surfaces, after which a more frequent application of solution of chloride of sodium or carbolic acid will deodorize them. A piece of carbolic soap is sometimes placed in such drain hoppers above the grating with much more reason than the use of a lump of charcoal for the same purpose. The soap is dissolved by the water thrown upon it, and its purifying properties brought into contact with the inner surfaces of the gratings and waste pipes, which the lump of insoluble charcoal can never reach."—*Sanitary Engineer.*

## REPORTED MORTALITY FOR THE WEEK ENDING MAY 6, 1882.

| Cities.                           | Population by Census of 1880. | Reported Deaths in each. | Deaths under Five Years. | Percentage of Deaths from         |                |                       |                |            |
|-----------------------------------|-------------------------------|--------------------------|--------------------------|-----------------------------------|----------------|-----------------------|----------------|------------|
|                                   |                               |                          |                          | The Principal "Zymotic" Diseases. | Lung Diseases. | Diphtheria and Croup. | Scarlet Fever. | Small-Pox. |

Deaths reported 2983 (no reports from New Orleans and Cleveland); 1112 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 689, consumption 465, lung diseases 381, diphtheria and croup 166, scarlet fever 126, small-pox 80, measles 62, typhoid fever 60, diarrheal diseases 56, whooping-cough 43, cerebro-spinal meningitis 35, malarial fevers 23, puerperal fever 18, erysipelas 15, typhus fever five. From measles, New York 25, Chicago 15, Brooklyn seven, Philadelphia six, Baltimore, Cincinnati, and Buffalo two each, St. Louis, Pittsburgh, and Milwaukee one each. From typhoid fever, Philadelphia 25, Chicago six, New York five, St. Louis four, Baltimore and Buffalo three each, Brooklyn, Cincinnati, Pittsburgh, and Lynn two each, Milwaukee, Nashville, Lowell, Cambridge, New Bedford, and Spencer one each. From diarrheal diseases, New York 26, Chicago and Boston five each, St. Louis four, Baltimore and Cincinnati three each, Buffalo and Nashville two each, Brooklyn, District of Columbia,

Pittsburgh, Worcester, Lynn, and Chicopee one each. From whooping-cough, New York 21, Brooklyn seven, Boston six, Chicago and Providence three each, Baltimore two, Cincinnati one. From cerebro-spinal meningitis, Buffalo 11, New York four, Philadelphia three, Chicago, Boston, St. Louis, Baltimore, and Worcester two each, District of Columbia, Providence, Fall River, New Bedford, Holyoke, Chelsea, and Weymouth one each. From malarial fevers, New York 11, Brooklyn five, Buffalo three, St. Louis two, Baltimore and New Haven one each. From puerperal fever, St. Louis four, New York three, Boston and Milwaukee two each, Brooklyn, Chicago, Buffalo, Lowell, Cambridge, Haverhill, and Newburyport one each. From erysipelas, New York four, Philadelphia, Brooklyn, and St. Louis two each, Chicago, Boston, Baltimore, Cincinnati, and Buffalo one each. From typhus fever, New York four, Buffalo one.

Two hundred and forty-eight cases of small-pox were reported in Cincinnati, Baltimore and Pittsburgh each 21, St. Louis 12, Brooklyn nine, Buffalo four, Milwaukee three, and Boston

one; diphtheria 34 cases, scarlet fever eight, typhoid fever eight, in Boston; scarlet fever 15, and diphtheria seven, in Milwaukee.

In 39 cities and towns of Massachusetts, with a population of 1,057,596 (population of the State 1,783,086), the total death-rate for the week was 20.34 against 22.27 and 21.36 for the preceding two weeks.

For the week ending April 15th, in 173 German cities and towns, with an estimated population of 8,559,514, the death-rate was 28.2. Deaths reported 4636: under five 2194; pulmonary consumption 716, acute diseases of the respiratory organs 557, diphtheria and croup 190, diarrhoeal diseases 163, scarlet fever 90, whooping-cough 76, typhoid fever 39, measles and röteln 35, puerperal fever 18, small-pox (Munich, Essen five, Koblenz two, Strasburg three) 11, typhus fever (Danzig, Berlin two) three. The death-rates ranged from 21 in Elberfeld to

44.6 in Nuremberg; Königsberg 26.2; Breslau 30.2; Munich 35.3; Dresden 28.9; Berlin 24.6; Leipzig 23.7; Hamburg 28.2; Hanover 20.9; Bremen 25.8; Cologne 29.8; Frankfurt 28.5; Strasburg 25.8.

In the 28 English towns, with an estimated population of 8,457,514, for the week ending April 22d, the death-rate was 22.7. Deaths reported 3677: acute diseases of the respiratory organs (London) 331, whooping-cough 214, measles 149, scarlet fever 70, fever 47, diarrhoea 43, small-pox (London eight) 17. The death-rates ranged from 16.8 in Halifax to 34 in Wolverhampton; Bristol 20.1; London 21.1; Leeds 21.3; Sheffield 21.9; Birmingham 23.1; Liverpool 27; Manchester 30.7. In Edinburgh 21.5; Glasgow 26.7; Dublin 36.3.

The meteorological record for the week ending May 6th in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the U. S. Signal Corps:—

| Date.            | Barom-eter. | Thermom-eter. |          |          | Relative Humidity. |            |             |       | Direction of Wind. |            |             | Velocity of Wind. |            |             | State of Weather. <sup>1</sup> |            |             | Rainfall.             |                   |

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MAY 6, 1882, TO MAY 12, 1882.

KING, WILLIAM S., colonel and surgeon. The extension of his leave of absence on account of sickness, granted him in S. O. 251, November 7, 1881, from A. G. O., still further extended six months on account of sickness. S. O. 104, A. G. O., May 5, 1882.

CLEARY, P. J. A., captain and assistant surgeon. The leave of absence on surgeon's certificate of disability, granted him in S. O. 224, October 4, 1881, from A. G. O., is extended six months on account of sickness. S. O. 107, A. G. O., May 9, 1882.

COWDRY, S. G., captain and assistant surgeon. Now awaiting orders, to report to commanding general, Department of the East, for assignment to duty at Fort Monroe, Va. S. O. 103, A. G. O., May 4, 1882.

HOLT, J. V. R., captain and assistant surgeon. To be relieved from duty in Department of the East, and report in person to commanding general, Department of California, for assignment to duty. S. O. 105, C. S., A. G. O.

CARTER, E. C., first lieutenant and assistant surgeon. To be relieved from duty in Department of California, and report in person to commanding general, Department of Arizona, for assignment to duty. S. O. 103, C. S., A. G. O.

RAYMOND, H. L., first lieutenant and assistant surgeon. To be relieved from duty in Department of California, and report in person to commanding general, Department of Arizona, for assignment to duty. S. O. 103, C. S., A. G. O.

#### BALTIMORE MEDICAL COLLEGES. A CORRECTION.

BALTIMORE, May 11, 1882.

MR. EDITOR.—In a communication from this city in the April 27th number of your journal signed "Papeau," appears the following statement: "We now have three schools of medicine: one giving a degree after two years of study; the others—for

the formation of both of which we have to thank (?) Dr. Edward Warren, late of Egypt, now of Paris,—"giving degrees after one year's study." There is but one school of medicine in Baltimore founded by Dr. Edward Warren,—the College of Physicians and Surgeons,—and of this school the statement that degrees are conferred after one year's study is unqualifiedly false.

At no time in the history of this school has any degree been conferred except after attendance on at least two full (winter) courses of lectures.

By making this correction you will greatly oblige,

Your obedient servant, THOMAS OPIE, M. D.,  
Dean, College of Physicians and Surgeons.

#### REDUCED FARES TO ST. PAUL.

MR. EDITOR.—Permit me, through the JOURNAL, to state that the Boston and Albany Railroad will sell tickets to St. Paul at \$17.60 each to members and friends attending the American Medical Association, provided the number going in party is not less than twenty. Should such offer be accepted a sleeper will be furnished for exclusive use.

The advised time of leaving Boston is by six p. m. train Friday, June 2d, arriving in St. Paul on Monday. Delegates desiring to avail of the above will address

HENRY O. MARCY, 116 Boylston Street.  
BOSTON, May 12, 1882.

The last meeting of the Surgical Section of the Suffolk District Medical Society will be held at 19 Boylston Place, Saturday, May 20th, at 7.45 p. m. Papers: Dr. J. W. Elliot, Fibromyoma Uteri; Dysmenorrhoea for Fifteen Years; Enucleation; Recovery. Dr. F. B. Greenough, The Rational and Routine Treatment of Venereal Diseases. Other material will also be presented.

H. C. HAVEN, Secretary.

DIED.—Suddenly, of peritonitis, at Longwood, the 15th inst., Marianne A. Amory, wife of Robert Amory, M. D., and daughter of Amos A. Lawrence, Esq.

## Original Articles.

## PERINEPHRITIC ABSCESS.

BY DR. G. H. LYMAN.

This case presents features of interest in the mode of origin, the coincident pregnancy, and the complications inducing a fatal result after obliteration of the abscess.

J. H., aged thirty-six, married, entered the City Hospital November 14, 1881. Ten months previously (January 19th) she was in the hospital for a week, with mild diphtheria, from the effects of which she appears never to have fully recovered. She had done little work for several months, and for two weeks before admission was confined to her bed. Eight months ago, that is, two months after the diphtheritic attack, she began to have frequent, sometimes painful, micturition, with "thick, muddy" urine, and frequent attacks of "jaundice" and constipation, these symptoms continuing until two months ago, when pain set in in the right side and back, extending down the leg to the ankle, and accompanied by daily chills morning and evening, followed by fever. For twelve days she has vomited everything taken. Her skin is now somewhat dusky, rather more so than other brunettes, the conjunctivæ clear, and no marked evidence of jaundice in the urine or faces. She has had two children, the last five years ago; no miscarriages. Menses very irregular, varying in occurrence from two weeks to three months, the last period being four months before entrance. Thinks that six weeks ago there was puffiness of the face and eyelids, and oedema of the left leg, but there is nothing of the kind now. The urine is slightly alkaline, contains one fourth per cent. of albumen, much pus, and numerous round epithelial cells; specific gravity 1008. The fundus uteri extends half way to the umbilicus; the abdomen is tympanitic; the breasts enlarged, and the areola dark, with enlarged follicles. Vaginal examination reveals a rupture of the perineum to the sphincter, with vaginal prolapse and varicose labia. There are evidences of old effusion in the right iliac fossa, but no extensive induration. She has had no cough, and the pulmonary symptoms are negative.

November 18th. Has had the bladder washed out at intervals with relief to the dysuria. The pulse has ranged from 100 to 116, and the temperature from 99° to 101° F. She is sure of the fetal movements, but neither fetal nor placental sounds are audible. Some fullness is now recognized on the right side, between the ribs and the crest of the ilium. Has had no rigors.

November 22d. Has been much the same; rather restless, occasional vomiting, and some dysuria. To-day she complains of a lancinating pain in the right lumbar region, extending down the thigh, and she sweats profusely upon the least exertion.

December 1st. On the right side a hard, obscurely fluctuating mass has developed, extending round from the navel to the spine, and from the crest of the ilium upwards until lost beneath the ribs (see diagram). Flatness, apparently from the displaced liver, extends nearly half way up the chest.

December 3d. The tumor was aspirated between the ribs and crest of the ilium, on a level with the um-

bilicus, but from a defect in the instrument only an ounce of fluid with a foul, fecal odor was withdrawn. This was mostly pus with some blood and granular detritus. The pus corpuscles were small and shriveled. The aspiration was followed by a chill and vomiting. Temperature 103.5° F. The following day, with the exception of some gastric irritability, she was perfectly comfortable, and without pain. On the 7th she had profuse sweats, but no rigor.

December 10th. The swelling was again prominent; sweating profuse; no rigors; ten and one half ounces fetid pus were aspirated, and the next day she expressed herself as much relieved, and perfectly comfortable.

December 16th. Has complained only of sweating and weakness until to-day, when vomiting recurred, and she is now restless and uneasy.

December 17th. Twelve ounces thick pus with fecal odor were withdrawn; the cyst is apparently much diminished.

December 21st. In consultation with Dr. Bowditch it was thought advisable, in view of the repeated refilling of the cyst, to make a free opening, and get permanent drainage, but on visiting her for that purpose to-day she was found to have been suddenly attacked during the night with severe spasmodic pain and excessive tenderness in the region of the tumor, with constant vomiting. Pulse 116; temperature 101.2° F.; no rigors; no general abdominal tenderness; countenance pinched, anxious, and haggard, and voice suppressed; respiration 60, and very shallow; flatness on

percussion extends upwards to about the fifth rib; the fundus uteri is now crowded to the left of the umbilicus. Her condition forbade any operative interference. The following morning her respiration remained unchanged; pulse 126, of fair strength, but in the afternoon her respiration fell to 36; she had dark green vomitus, and still a good deal of abdominal pain.

December 23d. After incision with history posteriorly, a large trocar and canula were tried without success, but with the longer aspirating needle four

<sup>1</sup> Read before the Section for Clinical Medicine and Pathology of the Suffolk District Medical Society, April 8, 1882.

ounces of greenish material, with fecal odor, was obtained, consisting of fat globules, granular detritus, bits of tissue, stained a bright yellow, and numerous crystals of irregular outline. (It is quite possible that the aspirator may have penetrated the edge of the liver, though there was nothing in the subsequent history to indicate it.)

December 24th. Less pain, swelling, and tympany; countenance better; tongue aphthous; micturition free and painless, but urine unchanged; there is not now, nor has there ever been, pus or blood in the dejections.

December 27th. Has been nourished mostly by injections; she now bears pressure over the tumor, the singular lateral prolongation of which towards the navel has disappeared; the abdomen is softer; the outline of the tumor in front is no longer recognizable to the eye, and only slightly so on the side, but is more visible behind; her countenance is brighter, and general condition much more hopeful; two ounces of pus aspirated.

December 28th. Has had four dejections of hard fecal masses, with profuse sweating, but the stomach retains nourishment and stimulants, and in every way she looks more promising; the uterus is less displaced, extending now three inches to the right of the navel.

December 29th. After a comfortable night the waters came at five this morning, and in an hour were followed by child and placenta. The child (a male, fourteen inches, hair and nails developed) lived but a few minutes. There has been no vomiting; the lochia are free and natural, and she says she feels well.

January 1st. Improves steadily; pulse 100, and strong; temperature normal; aphthae which have covered tongue and lips have disappeared; the skin is clearer; she has had no more sweating; she likes and retains her nourishment; has had a natural fecal dejection; there is no tumor perceptible to the eye or discoverable by palpation and moderate pressure, and she lies upon either side without pain; the abdomen is reduced not only to its normal size, but is flattened, the iliac bones projecting.

January 5th. The improvement continued until today, when the stomach again became irritable, the pulse feeble and irregular, the face flushed, and sweating profuse.

January 9th. Has steadily lost ground; is now unable to retain anything by the stomach; the aphthae have returned, and she is slightly wandering; complains only of weakness; no change noticed in abdomen. On the 10th she vomited blood freely, and clots were found in the dejections.

January 12th. Passed blood again by the rectum; she is greatly emaciated; no swelling or tenderness in epigastrium or elsewhere.

January 15th. Passed more blood yesterday, but to-day there is an improvement noted in her symptoms, which continued until the 18th, when she finally relapsed again, and died the 19th.

Though unusual efforts were made, it was impossible to verify the diagnosis in this case by an autopsy. At first the probabilities seemed to lie between an old pelvic cellulitis, resulting in suppurative extending upwards, coccal abscess, hepatic abscess, hydatid cyst, and suppurative kidney with perinephrite abscess.

The first vaginal examination, to be sure, revealed the evidences of old cellulitis on the right side, but there was neither pelvic heat, tenderness, nor swelling, and externally the outline of the tumor, after it be-

came perceptible, was not traceable downwards towards the pelvis, but distinctly upwards and laterally.

The locality, and especially the fecal odor of the pus obtained by the various aspirations, suggested the possibility of coccal abscess, but here, again, the evolution of the tumor was upwards and lateral, there was no history of typhilitis or intestinal obstruction, and no discharge of pus or blood by the rectum until long after the disappearance of the tumor and apparent convalescence. The fecal odor may well have arisen from contact of the mass with the intestines.

The attacks of jaundice, asserted by the patient to have existed in the early history of the case, suggested the liver as the possible seat of the disease, but there being no other symptom of hepatic derangement traceable, either at first or subsequently, than could rationally be accounted for by adjacent pressure, interfering with its blood supply or its excretory ducts, the inference seemed at least improbable.

During the earlier stages a fremitus, resembling that from hydatids, was felt at times in front, but its site was always resonant, and no hooklets were ever found in the pus obtained, though repeatedly sought for. The first fluid aspirated was not clear,—as would have been probable with an hydatid cyst,—but distinctly purulent.

The patient had, ten months previously, suffered from an attack of diphtheria, from the effects of which she had never fully recovered. Two months later she began to have thick, muddy urine with dysuria, and after another interval of six months, during which time pregnancy occurred, lumbar pains, extending down the leg, supervened, with daily chills and fever. When two to three months pregnant she had oedema, though lasting, apparently, but a short time. From first to last there was abundant pus in the urine. I suppose the case, therefore, to have been one of suppurating kidney, with perinephritic abscess, rapidly enlarging, and pushing the liver upward, displacing the lung, the whole influenced more or less by the pressure of an enlarging uterus. The abscess seems to have been entirely obliterated by the aspirations (in all forty-two and one half ounces of pus), it being lost sight of, and never refilling after the last operation, three weeks before death. Pus continued to discharge from the remaining sac of the kidney or its pelvis through the ureter, delivery took place, the tumor disappeared, and there was fair hope of recovery until, from some septic ulceration into stomach or intestines, a vessel was opened, and fatal exhaustion from hemorrhage ensued.

It would be interesting to trace, if possible, the connection between the antecedent diphtheria in this case and the primary renal symptoms which supervened two months later. Renal congestion and desquamative interstitial nephritis have been long sufficiently well established as common results of diphtheria, scarlatina, etc., but although tonsillar and post-pharyngeal abscesses do occur as sequelae of diphtheria, I am not aware of any well authenticated evidence of an actual suppurative process in the kidney traceable to such causes. Why it should be exempt from such results of pyæmic or septic blood changes as occur in other localities is not so clear.

—Dr. John Brown, of Edinburgh, died on May 11th. He was perhaps best known as the author of *Rab and His Friends*.

## NEPHRO-LITHOTOMY.

## RECOVERY OF COMPARATIVELY GOOD AND CONTINUOUS HEALTH DURING THE PAST EIGHT YEARS.

BY FRANK E. BUNDY, M. D., AND WILLIAM INGALLS, M. D.

OCTOBER 4, 1872, I was called to see Mrs. G. and attended her through a miscarriage. December 9th I was called again on account of excessive flowing, which had continued more or less since her miscarriage. It was at this time that she drew my attention to a trouble with her bladder, from which she had suffered for years. I learned the following concerning her previous history: She was thirty-one years old; her father died in California at the age of ninety-eight from the results of vaccination; her mother at the age of forty-five at the City Hospital after an amputation of the thigh, for disease of the knee-joint; she had four brothers and two sisters in good health; one brother had recently died of consumption. She was married at the age of fifteen, soon after her first menstruation. The menstrual discharge has always been profuse. She has had two children and two miscarriages. Her labors were natural.

In 1859, about two years after marriage, she began to suffer from frequent and painful micturition, which became so distressing that she finally submitted to an examination, which disclosed a uterine polypus as large as a good-sized orange; this was removed by Dr. Storer, and she regained perfect health.

In 1864, while sitting in a chair partially asleep, and resting the left side of her head on a table, she was struck from behind a severe blow on her right side and back with a chair. This blow was followed by severe illness, which obliged her to keep her bed for several days; she had great pain and soreness in the region injured, from which she never entirely recovered.

In March of the next year, 1865, on stepping from a horse car, she was seized with intense pain in the region of the right kidney; it was with great difficulty that she could be got home and into bed. The pain extended down the thigh and leg, and was so severe that morphia in large doses failed to control it, and she was kept for hours under the influence of ether; she had constant nausea and vomiting, and frequent, painful, and scanty micturition. She was confined to her bed for three weeks, and it was five weeks before she could use the right leg. She slowly recovered, but for more than a year at each menstruation she had a return of her distressing symptoms. She has never been free for any length of time from trouble while urinating. Some time in 1869 or 1870 she first noticed, in addition to the brick-dust sediment, which was almost constant, a deposit of thick white matter in the chamber; her distress increased rapidly, and finally the desire to pass water was so frequent at night as to seriously interfere with her rest, and she would frequently find herself asleep sitting on the vessel; she could relieve herself by pressing with her hands over the bladder, and forcing out what she said looked more like white soft soap than anything else. When about the house, she wore a napkin constantly. What follows is from notes.

December 10th. An examination of the urine

shows the amount and color natural, a large quantity of mucus, some pus, and a little albumen. A vaginal examination finds the uterus retroflexed, the fundus easily reached in the posterior cul-de-sac, and very tender; the depth of the cavity is five inches; the bladder is also retroflexed so that in passing the catheter the beak is turned backwards. There are several external hemorrhoids and evident disease of the rectum.

January 21th. Since last date, Mrs. G. has been treated with reference to the condition of her bladder and rectum. The bladder has been cleansed daily with carbolized water, and she has taken medicine internally; as a result, the organ is less sensitive, and the amount of pus and mucus is less. She has menstruated once, the amount of discharge being small, and attended with hemorrhage from the rectum and bladder. Ether was given, and three small hemorrhoidal tumors removed.

February 22d. Since the last date there has been but little change in the condition of the patient. Under ether, applied acaudal nitrate of mercury to several patches of diseased mucus membrane in the rectum. She has menstruated again, attended as before by a bloody discharge from bladder and rectum.

February 28th. Was called in great haste, and found that instead of using a soothing injection that I had ordered, Mrs. G. had injected an ounce of dilute nitric acid into her rectum. The pain and distress resulting from this accident continued for several days, but it was the last application needed for the rectum.

April 23d. Drs. Ingalls and Bixby in consultation. Since February 28th the history of the case has been, in short, as follows:—

February 29th, the day after the injection of the nitric acid, great pain was felt in the region of the liver; on examination a tumor was easily defined, hard, and excessively tender; this I took to be an enlarged liver. The area of dullness gradually increased for two weeks, until it extended down to within two inches of the crest of the ilium and anteriorly to within an inch of the umbilicus. The patient is compelled to lie on her back or right side, any attempt to turn on the left causing great pain. By the use of leeches, poultices, blisters, and tincture of iodine, the pain, tenderness, and swelling has diminished. For the last three weeks there has been almost constant nausea and frequent vomiting; she has complained of severe aching in her right side, and at times of excessive pain in the right umbilical and lumbar regions, and there is also a spot about the size of a half dollar, three inches to the right, and a little above the umbilicus, that is very tender on pressure. The pulse has been natural, except when suffering great pain; the tongue more red than natural, but always moist and free from coating. The bowels are constipated; she has no appetite, and her nights, as a rule, are rendered sleepless by pain. The bladder, although still sensitive, is much less so than it was two months ago. She passes during the twenty-four hours about four pints of urine, in which there are about four ounces of pus and but little mucus; the odor is highly offensive.

Although she has been in bed five weeks, has taken but little nourishment, has suffered almost constant pain, and had but little sleep, neither her strength nor flesh seem to be seriously impaired. She is bright

<sup>1</sup> Read before the Surgical Section of the Suffolk District Medical Society, March 25, 1882, by Dr. Ingalls.

and cheerful and invariably answers to my "How are you this morning?" "Nicely, I thank you."

Night before last she had a severe chill lasting an hour, and last night another.

After a careful examination and consultation, it was decided that either within the abdominal cavity or in the walls, there existed a collection of fluid, probably pus, and that the case might prove to be one of perinephritic abscess. It was decided to aspirate the tumor, and the point of excessive tenderness near the umbilicus was selected for the insertion of the needle. About one ounce of bloody fluid of an urinous odor was drawn and saved for examination. No ether was given, and the operation was well borne.

The next day, April 24th, Mrs. G. seemed none the worse, and in some respects better; she had passed a fair night, and, for the first time for many months, did not urinate from bed-time until morning. The nausea, which has been constant for three weeks, has entirely left her. She reports that after the operation yesterday, she passed from the bladder about a half cup of clear blood. The fluid drawn by the aspirator was examined and found to contain blood, pus, and albumen, and had a strong smell of urine.

The evening of April 24th was called in great haste. Found Mrs. G. suffering paroxysms of intense pain, which she said seemed like a cramp; it came on about noon in the small of her back, went through to her stomach, and then down into her pelvis; during the intervals, which last from three to ten minutes, she is perfectly free from pain. Large doses of opium and hot applications relieved her by midnight.

May 2d. Since the use of the aspirator the patient, with the exceptions mentioned, has been quite comfortable; has had little pain, little if any nausea, less frequent micturition, more sleep, and a better relish for food. The tumor seems to have decreased somewhat in size and is less tender. She averages about three pints of urine a day, in which there is from one drachm to one ounce of pus. She has taken tonics and a decoction of dog-grass. Large and hot flaxseed poultices have been applied, and the daily washing out the bladder with carbolic water continued. The capacity of the bladder is eight ounces.

Saturday, May 3d. Patient has had a bad night. No sleep on account of increased pain; her skin is sallow, her eyes dull and sunken, her face drawn and pinched, and her whole appearance indicates serious internal disease. Her pulse 72, weak and small, and her hands and feet are cold and clammy. The whole abdomen is swollen and tender, but especially over the tumor.

Sunday morning, May 4th. Dr. Ingalls in consultation. No improvement. When freely etherized an exploring trocar was pushed into the lumbar region between the eleventh rib and the crest of the ilium; a small quantity of bloody fluid followed. An incision about an inch long was then made into the cavity, from which escaped about four ounces of blood and pus. On passing the finger into this cavity, a considerable portion of the surface of the kidney could be felt; on the upper anterior part there was a small depression, in other respects it was natural to the touch. The operation was at ten o'clock; at noon she had a severe chill, with paroxysms of severe pain, such as followed the use of the aspirator; by three o'clock p. m. reaction was fully established. At eleven p. m. pulse 120; temperature 102° F. Tongue red and dry,

and face flushed. The pain is controlled by morphia, and a hot flaxseed poultice covers the entire abdomen.

Monday morning, May 5th. Had a bad night; in spite of the opium the pain is severe; it shoots from the side into the stomach and then into the pelvis. Pulse 118; temperature 102° F. Tongue red, dry, cracked, and centre covered with a brown coat. Abdomen much distended with gas. No indications of peritonitis. Takes beef tea, brandy, and morphia. Eleven o'clock p. m. Perhaps less pain this afternoon; has made and signed her will. Thirteen ounces of urine were drawn, pinkish in color, no odor, and no pus apparent. Pulse 130; temperature 102° F. The whole side is very sore, and she moves with great difficulty.

Tuesday morning, May 6th. Dr. Ingalls saw the patient with me. Had a better night, seems brighter and more hopeful. Pulse 110; temperature 102° F. Tongue red, but moist. Suffers from tympanitis. The region of the wound is very tender, and there is a small discharge of pus. Washed out the bladder, changed her clothes, and moved her to the other side of the bed, all of which she bore well. A portion of her urine taken yesterday was examined with the following result:—

Reaction acid. Sediment one fourth inch, pink, and consisting of urates. Albumen present in considerable quantities.

By microscope—Granular casts and pus in small quantities.

Tuesday evening. Pulse 118; temperature 100.7° F. Drew ten ounces urine free from pus, and natural in appearance.

Wednesday morning, May 7th. Looks bright and cheerful; her face has lost its sallow hue. Pulse 110; temperature 100° F. Tongue red, but quite moist. There is a discharge from the opening of a thin, colorless, and odorless fluid which keeps her constantly wet. The discharge of pus does not amount to more than one ounce in twenty-four hours.

Thursday, May 8th. Not so well this morning; had more pain last night. I drew six ounces of urine. The discharge of fluid from the opening is profuse.

Friday, May 9th. A decided improvement. Pulse 96, of fair strength; temperature 98.75° F. Tongue more healthy, and she has more appetite. Less tympanitis.

Saturday, May 10th. Had a good night. Pulse 76; temperature 98.75° F. Was moved into a large room.

May 18th. Mrs. G. has been slowly, but surely, gaining; she sits up in bed, has been moved to a lounge, and says she feels strong enough to walk; she takes a fair quantity of food with good relish. The appearance of the abdomen is natural, and the region of the kidney still somewhat tender on pressure. The average amount of urine passed for the twenty-four hours has been until to-day seven ounces; to-day she passed sixteen ounces, and with the exception of a little pus, it looked natural. The discharge of pus from the cavity has increased, and the amount of fluid is so profuse as to cause great annoyance, frequently wetting through two large folded sheets, and often at night wetting her clothes, her pillows, and even her hair.

From the last date, May 18th, to October 1st there accrued in the progress of the case nothing of importance. She spent her time between the bed and lounge, was able to take a few steps about the room,

and twice rode out. The amount of urine passed was variable, depending, as it seemed, on the quantity of discharge from the side. On two occasions she had retention of urine for twenty-four hours, relieved, as she expressed it, by something giving way, and followed by a large quantity of blood.

On September 17th I gave to Dr. Clement four ounces of the discharge from the cavity, and the same amount of urine, for examination, which he kindly made, and gave me the following report: "The specimen of urine contains albumen, pus, and blood cor-

puscles. The other specimen contains albumen, pus, blood, crystals of triple phosphate, and, with nitric acid, a few crystals of nitrate of urea."

October 1st. Drs. Cheever, Ingalls, and Blake in consultation. For several days the discharge from the cavity has been gradually decreasing; the abdomen is much distended, and the region of the right kidney painful and tender. After consultation it was decided that removal of the kidney should be advised, or, the patient not consenting to this operation, a free incision should be made, allowing a more ready escape of the discharge.

October 8th. There being no improvement in her condition, and Mrs. G. refusing to submit to the grave operation of removal of the kidney, it was decided to make a free opening.

The operation was done by Dr. Ingalls, who furnished, in a few days after, the following description:—

"The sinus being narrow, barely admitted the director, which entered a distance of one and a half inches. With a scalpel upon the director, an opening was made large enough to admit the forefinger, which passed downwards, and a little forwards, into a sac or cavity, which was smooth to the touch, and of the length, nearly, of the finger, and otherwise a little larger. No fluid escaped through the incision other than a small quantity of blood. As, evidently, the purpose for which the operation was made was not accomplished, the finger searched for and found a narrow opening at the upper end of the inner side of the cavity mentioned, and nearly opposite to the point of entrance of the director within it. Introducing the director into this newly-found orifice, it was passed onwards, easily, its whole length, and upon this the scalpel was plunged to the end, and a little beyond, when there gushed forth a quantity of the same kind of fluid which had been flowing for so long a time through the sinus. There were six measured ounces, and at least two ounces more which were not caught. The finger was now introduced as far as possible, and entered a cavity with ragged walls, the size of which I venture to compare to that of a full-grown horse-chestnut. Searching this, at the posterior wall, the finger came in contact

with what seemed to be a calculus, and which proved to be one. Little by little the soft substance embracing the stone was loosened by the finger, and finally the larger fragment was withdrawn by the aid of forceps, and in a few moments, by the same process, the smaller piece; two small fragments broke off at the first touch of the finger.

"The stone, with its fragments, weighs ten drachms and four grains."

This operation was followed, as the other had been, by days of severe illness, attended with high fever and great pain. The patient gradually improved, and in eight weeks was able to be moved to her reclining chair.

January 28, 1874. The discharge having again diminished, owing to a closing up of the sinus, followed by increased pain, swelling, and tenderness, another operation was made by Dr. Ingalls. The original sinus was enlarged to the bottom of the cavity. The probe entered four and one half inches. At a point two inches to the right, and a little above, another opening was made, and the two connected by rubber tubing.

April 15, 1882. The history of this case for the last eight years can be condensed into a few lines.

The rubber drainage tube was retained for three days, and then escaped, and all subsequent attempts to replace it or to assist nature in keeping the cavity well drained were futile on account of the great tenderness of the sinus. In October, 1874, after two or three days of diminished discharge, Mrs. G. was seized with a severe chill, which lasted several hours, during which time she was unconscious. I was sent for, but being out of town another physician was called. On my return I learned that after the chill she had several copious evacuations from the bowels, which resembled in appearance and odor the discharge from the side. I am unable to say positively, but my opinion is that the over-distended cavity found a vent through the intestine. This chill was similar to though more severe than several which she has had since 1874; the last occurred about six months ago.

In June, 1876, she was able, with the aid of crutches, to take a few steps about her room; since then she has been constantly improving, and is now able to walk and ride without discomfort, and says that, with the exception of the soreness in her side, she feels perfectly well.

When the sinus is discharging freely the right side is smaller than the left, but if the flow is hindered the right lumbar region becomes swollen and tender. She is unable to lie down, and sleeps sitting up in bed, any attempt to lie down bringing on severe cramps in her side. Her urine is natural in appearance and quantity.

The greatest annoyance has arisen from the profuse discharge from the sinus: until two years ago she used large quantities of cloth, wads of tow, or a sponge, to absorb this fluid; at that time, at my suggestion, Dr. Green, of Leach & Green, undertook to contrive something for her relief, and the result is all that could be asked for. The apparatus consists of a silver plated reservoir and shield, concave on its inner surface, and convex on the outer. The plate forming the inner surface only covers the lower half, and its upper edge forms a flange, which fits so accurately to the body just below the sinus that all discharges must drain into

the receptacle below. The outer plate extends high enough to completely cover and protect the opening from contact with the clothing. It is held in position by a suspender from the opposite shoulder, and a belt around the hips. To the lower extremity of the reservoir is attached a short rubber tube leading to a rubber bag, holding a pint. The inlet to this bag is provided with a valve, to prevent reflow, and also a stop-cock at its lower extremity, by which its contents can be drawn off. This bag she is obliged to empty, on an average, twelve times during the twenty-four hours.

## OBSERVATIONS ON CATARRHAL FEVER.<sup>1</sup>

BY J. M. DA COSTA, M. D.,

*Professor of Practice of Medicine in Jefferson Medical College.*

THOSE engaged in active medical practice must have been struck with the widespread prevalence of an epidemic of catarrhal fever presenting many curious features. As it is only by a study of all such epidemics that we shall ever learn fully to understand this dissimilar malady, I trust it may not prove without value to record before the College my individual experience with it.

The disorder begins almost invariably in a sudden manner, sometimes with a chill, quite as often without it. I have known persons well in the afternoon, and in the evening with a decided fever, and suffering all the discomforts of the catarrhal malady. Among the first signs of this are pain in the throat, and a feeling as if it were filled up, yet looking at it nothing is seen but redness and some relaxation. Fever is by this time developed, at first of only moderate intensity, and with a quick but very compressible pulse. Dry cough soon becomes a feature, occurring not infrequently in paroxysms, and now and then combined with loss of voice, and with difficulty in swallowing. The chest walls are sore, and the cough is painful. Frequent, rather difficult breathing, not associated with any marked physical signs except feebleness of respiratory murmur, is a common symptom. As the malady progresses, more obvious signs of bronchial catarrh may happen, and harsh breathing and dry râles be found on listening to the chest. But here and there will be a spot still marked by feeble breathing, a spot of seeming congestion of the lung and of impaired expansion. Scanty tenacious sputum, blood streaked, is perhaps noticed, to become more copious and purulent only in cases in which the bronchial catarrh is prominent. The eyes are, as a rule, injected or watery, but nasal catarrh does not exist. Yet late in the disease it may come on, and the malady pass off, in the language of the patient, by a bad cold in the head. Besides these catarrhal symptoms, are pains, — chest pains, pains in the neck and scalp, pains in the loins and limbs. The chest pains are most peculiar and severe. They are sharp and like pleurisy, indeed they are so regarded. But only impaired respiration exists, friction does not, save in the rarest instances; and the character of the pain, its having its seat in the chest walls, is shown by its transferring itself with rapidity from one side to the other.

As regards the nervous symptoms, great lassitude, restless nights, and marked hebetude strike us most.

<sup>1</sup> Read before the College of Physicians of Philadelphia.

With reference to the drowsiness, it is often so decided that it is difficult to believe that the patient has not taken opium. Delirium I did not once encounter, nor were the cutaneous hyperæsthesiæ as common as I have noticed them in other epidemics. In truth, on the whole, the nervous phenomena, except the hebetude, were less pronounced.

The duration of the disease is a short one. It does not, unless kept up by complications, exceed a week; nor did I see a fatal case unless from complications. During the rather tardy convalescence, what forces itself on our attention is the weakness with the decided loss of flesh which so short a disease has occasioned. Of course, I am speaking only of marked cases, and not of the slight ones of a few days' duration that abound as a light manifestation of the epidemic influence. Glandular enlargements are very occasionally met with during the convalescence; more often did I notice inflammation of the antrum with its distracting headache and sense of fullness and pain.

I have just alluded to the complications. Pneumonia, catarrhal and lobar, is the most common. And I am quite clear that the great prevalence just now of pneumonia must be mainly ascribed to the influence of the poison of the catarrhal fever. But this is too large a question to enter into here, as it would equally lead me too far to inquire whether there are any clinical differences which separate these pneumonias of epidemic origin from those originating from other causes.

Besides pneumonia, I have met with overwhelming attacks of pulmonary congestion. One, for instance, seen with a medical friend in which a bright lad of sixteen perished who had not been ill forty-eight hours; perished with bloody tenacious sputum, temperature of 104.8° F., intense dyspnoea, heavily congested lungs, terminating in œdema, and amid vanishing pulse, wild struggles for life, and signs of non-aerated blood, in whom, nevertheless, there were no spots of dullness or bronchial breathing or other evidences of consolidation to be detected. Then I saw, with Dr. Herbert Norris, in a previously healthy, although rather delicate, young woman, who was seized with catarrhal fever just as her little girl was fairly convalescent from it, rapid phthisis develop itself, primarily in the lung which, three or four days after the acute setting in of the catarrhal malady, had slowly advanced to imperfect consolidation at its lower part, then more rapidly in the right. On the side first affected a large cavity formed in the lower lobe, and became manifest on about the twelfth day of the disease. The whole duration of the case was just three weeks; the only instance of tubercular affection to be traced in the family was that of an aunt.

The state of the skin is at first dry and harsh. It becomes soft and clammy as the disorder advances, and copious sweats, especially at night, are common. The face at the outset is apt to be flushed, and what has particularly struck me in this epidemic as a feature which I cannot recall to have noticed so strikingly before, is a curious irregular mottling of the surface. This is very marked on the neck and breast, and might easily cause the case to be mistaken for scarlet fever or for German measles. But when closely looked at, it is seen that the capillary injection is really quite unlike the eruption of either.

As temperature observations on catarrhal fever are very imperfect, I recorded whenever a good opportu-

nity offered as many as possible. Here is a case in which with the aid of a very intelligent nurse they were made three or four times daily, and begun a few hours after the first symptoms had manifested themselves.

1st day. 2.30 A. M., 102.2° F.; 6.45 A. M., 100.8° F.; eight P. M., 101° F.

2d day. Eleven A. M., 100.8° F.; nine P. M., 101.6° F.

3d day. Two A. M., 104° F.; 10.30 A. M., 101.5° F.; three P. M., 101.5° F.; six P. M., 103° F.; nine P. M., 105° F.

4th day. Seven A. M., 101.5° F.; nine A. M., 99.5° F.; eleven A. M., 100° F.; six P. M., 100° F.

5th day. Eleven A. M., 99.92° F.; nine P. M., 99.6° F.

6th day. A. M., 99° F.

7th day. A. M., 98.5° F., no evening rise.

This temperature was the highest I have met with in an uncomplicated case. It attained its height on the third day, and is seen to be very irregular. In truth, irregularity of temperature is one of the characteristic features. The temperature is apt to be irregular until the whole disorder markedly declines, when it by gradual degrees, but in the space of a day or two, returns to the normal.

Next to the catarrhal and febrile symptoms the gastro-intestinal claim attention. Disgust for food, pasty tongue, are very usual, and attacks of diarrhoea not unusual. In some cases, indeed, the intestinal catarrhal symptoms are far the most prominent, and it may be that only with their subsidence the bronchial catarrh appears. Nor is it always a simple diarrhoea. Seizures bespeaking an irritation of the large intestine, diarrhoeas soon merging into dysenteries, form quite a fair proportion of the cases. The urine is high colored, scanty, but free from albumen, even in cases with a temperature of 105° F. Only in instances of most marked pulmonary congestion have I known it to contain albumen, and then but in small quantities.

Another complication I have met with is gangrene of the lung. I saw such a case with Dr. Girvin. The sputum was horribly offensive, the wasting decided; a spot at the upper part of the left lung was gangrenous. These symptoms had set in acutely, about ten days after an attack of catarrhal fever in a young woman before in good health.

There is generally little difficulty in the diagnosis of the epidemic malady; the catarrhal symptoms, the signs of the general disorder, are very manifest. Occasionally a puzzling case happens; as, for instance, one in a young girl with nosebleed, with diarrhoea, with high temperature, all within the first week of the disease. Yet the sequence of the phenomena prevented the affection from being mistaken for typhoid fever. The nosebleed came on after the marked catarrhal symptoms; the diarrhoea appeared on the fourth day, and lasted only forty-eight hours; the high temperature continued but for a day, and then there were very irregular variations until, by the eighth day, the temperature had declined to normal.

One of the most interesting features of the present epidemic is its infectious character. In one household five members took it in succession; in another, it began with grandchild and ended with grandmother, after two children, mother, and three servants had had it. Nor are those exempt who are confined to

the house. One of the most marked cases I encountered was in a lady who has been for five years bed-ridden; in another, the patient had not been out of doors for ten months.

As regards the treatment, I have nothing to add to what is well known. It has to be symptomatic; and in the very young and the very old decidedly supportive. My experience, however, makes me urge the advantage of employing quinine almost from the start; and has taught me that small, repeated doses of opium have a most happy, steady, and distress allaying influence.

## RECENT PROGRESS IN PATHOLOGY AND PATHOLOGICAL ANATOMY.

BY WM. F. WHITNEY, M. D.

### THE ETIOLOGY OF TUBERCULOSIS.

ALL the work which has been done up to the present time points to the probability of tuberculosis being an infectious disease, and further, that the virus is intimately associated with an organized ferment. This, however, has never as yet been demonstrated as a definite morphological form, capable of isolation and cultivation outside of the body. Nor have the results of the cultures which have been attempted ever with positive certainty reproduced the disease. During the past week an article by Dr. Robert Koch, of Berlin,<sup>1</sup> whose work on the infectious diseases of wounds and the etiology of malignant pustule (anthrax) has placed him at the head of investigators of such subjects, has appeared, in which he proves as clearly as is possible without the direct inoculation of human beings the dependence of tuberculosis upon an organized virus, and the identity of the forms found among animals and men. The importance of this discovery demands more than a brief summary.

A peculiar method of coloring enabled him first of all to discover the parasite, which had escaped the eyes of all previous investigators. The objects were either examined fresh or after hardening in absolute alcohol. If the first method was chosen a little of the material from recent tubercles was spread as thinly as possible upon a cover glass and exposed to a heat of from 120° to 130° C. for from two to ten minutes. If the tissue had been hardened it was cut in the ordinary manner. The sections or cover glasses are placed in a coloring solution of the following composition: 200 centimetres of distilled water are mixed with 1 centimetre of a concentrated alcoholic solution of methyl blue, this is well shaken, and to this is added under constant agitation 0.2 centimetres of a ten per cent. solution of caustic potash. The objects remain in this from twenty to twenty-four hours, which can be reduced to half an hour by placing them in a water bath heated to 40° C. After removal from this they are at once placed in a watery solution of vesuvium (which must be filtered before each time of using) and then washed with distilled water for from one to two minutes. The sections are to be dehydrated by alcohol, which is replaced by oil of cloves, and then examined in that or mounted in Canada balsam. In these preparations the constituents of the tissue appear brown, while the tubercle bacteria remain of a deep blue color, and can thus be readily distinguished, even when present in small numbers.

<sup>1</sup> Berlin. klin. Wochenschr., April 10, 1882.

The bacteria thus made evident have certain peculiar characteristics. They are staff shaped, and thus come under the group of bacilli. They are very thin and one quarter to one half as long as the diameter of a red blood corpuscle. They are very similar to the bacillus of leprosy, but differ by being slimmer and pointed at the ends.

The bacilli are present in large numbers where the tuberculous process is fresh and making rapid progress. They are usually found thickly pressed together, often in little bundle-like groups situated in the interior of cells, as are also the bacilli of leprosy. Near at hand are found numerous free bacilli, especially on the borders of the large cheesy foci, where they occur in great masses.

As soon as the acme of the eruption is reached the bacilli become fewer, are found only in small groups, or entirely isolated on the borders of the nodules. These take color very feebly, and at times are scarcely to be recognized, and are probably in the process of destruction or already dead. Finally they can entirely disappear, yet this is very rarely the case, and only where the process has come to a standstill.

When giant cells occur the parasite lies in their interior, and in the slowly progressive forms of disease this is the only place where they are to be found. In this case the greater number of giant cells contain one or two bacilli, and it makes an astonishing impression to see each new group of cells containing these diminutive blue-colored rods, almost pendulous in their centre. From their size and position it is probable that the giant cells which contain the bacilli are the youngest, while those in which they are not found are older. They probably have contained the parasite at one time, which has been destroyed or passed into the stage of permanent spores.

The bacilli can also be seen in uncolored preparations. For this purpose a little of the substance must be taken from a place that contains large numbers of them, for example, from the gray tuberculous nodules of the lung of a guinea-pig, and examined in a little distilled water, or better, in blood serum. In order to prevent currents in the liquid a hollowed object glass slip is to be used. The bacilli appear as very fine rods which show only a slight molecular movement, but do not possess the slightest automatic motion.

Spores are formed even in the animal body, under conditions to be described later, and a single bacillus may contain several, usually two or four of an oval form, placed at equal distances throughout the length of the rod.

In the various tuberculous affections of men and animals bacilli have been found as follows: (1.) From man. Eleven cases of milary tuberculosis. They were never missed from the nodules in the lungs, but only to be found, however, in the periphery of those with cheesy centres. They could be found in the tubercles of the spleen, liver, and kidney, and were especially abundant in the gray granulations of meningitis basilaris. The cheesy bronchial glands often contained a thick swarm of the parasite, many of which carried spores.

Twelve cases of cheesy bronchitis and pneumonia, in six cases with formation of cavities. The occurrence of the bacilli was restricted to the edge of the cheesy infiltrated tissue, but they were very abundant. In the exudates they were found in great quantities, the little cheesy bits which are found there consisting al-

most exclusively of masses of the parasites. Several cases containing spores were found in these localities. In the larger cavities they were found mixed with other bacteria, but were easily distinguished by their color.

One case of solitary tubercle of the brain. This was extensively cheesy, and only a few were found in the giant cells in the periphery.

Two cases of intestinal tuberculosis. The bacilli could be easily made out in the nodules, especially in the youngest and smallest, which were grouped about the ulcerations. They were also present in great numbers from the mesenteric glands belonging to these two cases.

Three cases of freshly extirpated scrofulous lymph glands were examined, and the bacteria could be found in but two, and then only in the giant cells.

In two out of four cases of fungous inflammation of the joints the parasites were also seen, but in small numbers.

(2.) From animals. Ten cases of tuberculosis of cattle were examined. These had the customary cretaceous masses in the lungs, peritoneum, and once in the pericardium. In all the cases the bacilli were detected especially in the giant cells in the tissue inclosing the cretaceous masses. The distribution of these was so regular that there was not a cell which did not contain from one to twenty parasites. In one case they were distinguished in the bronchial and in another in the mesenteric glands.

In three cases of cheesy bronchiectasis the bacillus was met with in the tissue of the periphery.

A cheesy cervical gland from a pig contained the same bacillus.

In the organs of a hen, dead from tuberculosis, the medullary portions of the bones, the large nodules of the intestines, in the liver and lungs, a large number of the tubercle bacillus were found.

In three tuberculous monkeys the parasite was found in the numerous nodules which studded the lungs, spleen, liver, and omentum, and the cheesy lymph glands in their neighborhood.

In nine guinea-pigs and seven rabbits, which had developed tuberculosis spontaneously, were the bacteria seen in the milary granulations.

Besides these cases of spontaneous tuberculosis there was a great number of animals which became tuberculous after infection with the various tuberculous substances, namely, the gray and cheesy tubercle of human lungs, the sputa of consumptives, tuberculous masses from apes, guinea-pigs, and rabbits, and the cheesy and cretaceous masses from the lungs of cattle, and finally, the results of the inoculated disease. The number of animals thus used was one hundred and seventy-five guinea-pigs, thirty-two rabbits, and five cats. In every case were bacilli found, often in great numbers, and frequently containing spores.

From these numerous observations the author holds it to be proved that in all the tuberculous affections of man and animals there occurs a characteristic bacterium (which from its smallness and peculiar reaction with coloring reagents had escaped the previous observers). This Koch has designated as the tuberculous bacillus.

From the occurrence together of tuberculous processes and this bacillus, it does not follow that they stand in relation of effect and cause, although a certain degree of probability is given to this assumption from

the fact that the bacilli are especially to be found where the disease is in progress, and disappear when it has come to a stand still.

In order to prove this, however, the parasite must be isolated from the body and bred in a pure medium, until they are freed from all the products of disease arising from the animal organism, and finally the carrying of these isolated bacilli into previously healthy animals must produce the same disease, which, according to experience, has been produced by the inoculation of tuberculous material produced in the natural course of disease.

The method employed for the cultivation of the bacilli was as follows: Serum from the blood of cattle or sheep, obtained as pure as possible, was placed in beaker glasses and stopped with cotton wool and submitted to a temperature of  $58^{\circ}\text{C}$ . during an hour for six days in succession. By means of this expedient the serum was sterilized in the majority of cases. The serum appeared after this operation as an entirely transparent, or only slightly opalescent, almost gelatinous mass. If the temperature rises above  $75^{\circ}\text{C}$ . or is continued too long it becomes opaque.

The tuberculous material is brought upon this prepared blood serum in the following manner: The fresher the material the more likely is the experiment to succeed. For this purpose an animal that has become tuberculous by inoculation or otherwise is killed. The skin of the breast and side is cut through with a knife which has been previously "fired." The ribs are next separated, all the instruments having been thoroughly fired. The anterior chest wall is next removed, care being taken not to open the abdominal cavity, and the lungs are thus exposed to a large extent. The instruments are then exchanged for others carefully disinfected by fire, and single tubercles or patches of the size of a millet seed are quickly separated and immediately transferred to the stiffened jelly by means of a "fired" platinum needle. It goes without saying that the cotton wool plug is to be exposed to the air for as short a time as possible. In this way six to ten glasses should be sown, all of which, even with the greatest care, will not remain absolutely free from impurities.

The culture from human lungs, or from the "pearly" masses of cattle, is much more difficult, yet it has succeeded in the hands of Kock.

The glasses thus sown are to be placed in a constant temperature apparatus, and must be persistently maintained at a temperature of from  $30^{\circ}$  to  $37^{\circ}\text{C}$ . During the first week there is no special change. If any occurs during this time, such as the formation of gray or yellow drops, often with the liquefying of the medium, it is a sign of the presence of impurities, and those glasses must be rejected.

The culture proceeding from the growth of the tuberculous bacillus appears first to the unaided eye, about the tenth day, as little dry points or scales surrounding the bits of tuberculous material. By the aid of a low power, thirty to forty diameters, the colonies of bacilli can be distinguished towards the end of the first week. They appear then as very tender spindle, often S or irregular shaped masses, which, when spread thinly upon a cover glass, colored, and examined with the highest powers, are seen to consist entirely of the very finest bacilli. The growth of these colonies goes on for from three to four weeks. They increase to flat scales, never exceeding the size of a poppy seed,

which lie loosely upon the jelly, which they never cause to liquefy, or into which they never penetrate.

The colonies of bacilli form so compact a mass, that the small scale from the stiffened serum can be lifted up intact by a platinum needle, and can only be broken by using some little force. The exceedingly slow development, which is only obtained at a constant temperature, and the peculiar scaly, dry, firm consistency of these colonies do not occur in the growth of any other known kinds of bacteria, so there is no possibility of confounding the tubercle bacillus with any other.

After several weeks the growth of the colony is ended, owing probably to the fact that they have no automatic motion, and are pushed over the surface of the jelly simply by their increase in size. In order to preserve such a culture in progression it must be carried on to a new soil on the tenth or fourteenth day. This is accomplished by lifting a scale on the point of a "fired" platinum needle, and transferring it to a fresh sterilized glass, where it is to be broken up and pressed out as much as possible. There occur then in the same period the same dry, scaly masses which become confluent. In this way the culture is continued.

In order to meet the objection that from the inoculation of the tuberculous masses in guinea-pigs before the cultivation, a change in the nature of the bacillus could be produced, an attempt was made to cultivate the tubercle bacillus directly from the spontaneously affected organs of men and animals. These experiments succeeded several times, and there was obtained a pure culture from two human lungs with miliary tubercle, from one with cheesy pneumonia, twice from the contents of phthisical vomica, once from cheesy mesenteric glands, and twice from freshly extirpated scrofulous glands. Further, twice from "pearly" lungs of cattle, and three times from the lungs of guinea-pigs spontaneously affected with tuberculosis. These cultivations were all exactly similar to each other and to those which were obtained by the circuitous route of first inoculating guinea-pigs, so there is no doubt as to the identity of the bacillus in the different tuberculous processes.

In regard to the results of pure cultivations he remarks that Klebs, Schuller, and Toussaint have also obtained micro-organisms after the culture of tuberculous masses. But all of these investigators found that their fluids became cloudy after two or three days. In the experiments of Klebs small, quickly moving rods appeared, while Schuller and Toussaint obtained micrococci. The author, on the other hand, has repeatedly convinced himself that the true tubercle bacillus grows but poorly in fluids, never makes it cloudy, and are entirely immovable. Development, moreover, does not take place before two or three weeks. These investigators, therefore, must have had to do with other than the tubercle bacillus.

Up to this point it is certain through his investigations that the occurrence of a characteristic bacillus is regularly joined with tuberculosis, and that these bacilli can be obtained from tuberculous organs and isolated in pure cultures. There still remains to be decided the important question whether the isolated bacilli when they are again brought into the body can reproduce the disease.

In order to exclude every error, in the solution of this problem, in which the difficulty of the entire ex-

periment lies, as many series of experiments as possible were arranged.

In the first series of experiments the animals were inoculated by introducing a fragment of the material into the subcutaneous tissue of the abdomen. The material for the cultures for this series was obtained from the following sources: (1.) From human miliary tubercles of the lungs and bred for fifty-four days before using. (2.) From the lungs of an ape, bred ninety-five days. (3.) From the lungs of tuberculous cattle, bred seventy-two days. (4.) From the lungs of a monkey, and bred one hundred and thirteen days.

Guinea-pigs were chiefly used for this series, and one or two animals in each set were kept under the same conditions, with the exception of inoculation, for control. This rule was always observed in all subsequent experiments. The results of these experiments were all exactly similar, and showed that the inoculation of the bacillus culture in the abdomen produced the same inoculation tuberculosis as if fresh tuberculous material had been brought into the animal.

The next series was the inoculation of the results of various cultures for varying times in the anterior chamber of the eye of rabbits. In all the cases there appeared after the regular period of incubation, first, the iris tuberculosis, and later the general affection, corresponding exactly with the observations of Conheim, Solomonson, and Baumgarten, who had employed the fresh material.

He instituted further experiments by injecting the bacillus culture into the abdominal cavity and directly into the blood stream. By this method he also succeeded in producing the disease, while the animals which had received simply an injection of blood serum unmixured with bacilli remained entirely free from trouble. Further by this same means animals, such as rats and dogs, which are not liable to spontaneous tuberculosis, could be inoculated, and the characteristic appearances were found after death.

The syringes used for these experiments were disinfected by submitting them to a heat of 160° to 170° C. for an hour before using.

The tubercles which followed the inoculation presented the same histological structure as did those which originated spontaneously, and the bacilli were found in the giant cells in the same manner.

In summing up the results of his experiments the author says it is seen that in no small number of animals into which the bacilli were introduced in various ways, namely, by injecting into the peritoneum or anterior chamber of the eye, or directly into the circulation, or by inoculation in the subcutaneous tissue, all became tuberculous without exception, and there was found not only separate nodules but an extraordinary number of tubercles in the organs corresponding to the quantity of the infectious germs. In other animals the inoculation of a very small number of bacilli in the anterior chamber of the eye produced exactly the same tuberculous results that Conheim and others had obtained by the inoculation of pure tuberculous substance only.

A mistake for spontaneous tuberculosis or the accidental infection of the animal by spontaneous tubercle virus is excluded on the following grounds: (1.) Neither a spontaneous nor accidental infection can cause such an extensive eruption in so short a time (twenty-five to thirty days being the average for the full development of the inoculated disease). (2.) The

control animals which were treated in exactly the same way as the infected animals, except that they received no bacilli, remained sound. (3.) There has never occurred in the numerous animals he has injected for other purposes with various materials at various times this typical picture of miliary tuberculosis, which can only occur when the body is overwhelmed at one time with a large quantity of the infectious material.

All these facts taken together warrant us in the assumption that the bacilli occurring in the tuberculous substance are not the accompaniment of the process, but that we have before us the tuberculous virus itself.

With this there is also furnished the possibility of defining what is to be understood by tuberculosis, which before this could not be done with certainty. There was wanting a definite criterium for the disease. Some reckoned to miliary tuberculosis, phthisis, scrofulosis, pearly distemper, etc., while others held all these processes for distinct. In the future it will not be difficult to decide what is and what is not tubercle. Not its peculiar form, nor its want of vessels, nor the presence of giant cells will give the criterium; but the knowledge of its bacillus, be it in the tissue by the color test, or be it by culture on coagulated blood serum. This, then, taken as the standard must, according to his experience, declare miliary tuberculosis, cheesy pneumonia, cheesy bronchitis, intestinal and gland tuberculosis, "pearly" distemper of cattle, spontaneous and inoculated tuberculosis of animals, for one and the same. On scrofulous and fungous disease of the joints his experience does not allow him to give a decision.

The occurrence of the tubercle bacillus in the cheesy gland of a pig, and in the nodule from a hen, cause it to be suspected that tuberculosis has a wider spread among the domestic animals than is generally supposed, and it is greatly to be desired that its distribution in this direction could be exactly learned.

After the parasitic nature of tubercle is determined, in order to complete the aetiology of the disease the question must be answered where the parasite originates and how it gets into the body.

In respect to the first question it is necessary to decide whether the infectious stuff is only developed under relations which are met with in the body, or if, as in the case of the bacillus of malignant pustule (anthrax), it can also go through its stages of growth entirely independent of the animal organism. The result of several experiments showed that the tubercle bacillus only grew in a temperature between 30° and 41° C. Under 30° as well as at 42° C. there was not the slightest growth in three weeks. While by way of contrast the anthrax bacillus grew vigorously at 20° C., and between 42° C. and 43° C. On the ground of this one fact the question can be decided. In the temperate climate there is no opportunity outside of the animal economy for preserving a temperature of at least 30° C. for two weeks without change. It follows from this that the bacillus tuberculosis arrives at its development solely in the body, also that it is not an accidental but a real parasite, and can only arise from the animal organism.

The second question as to how the parasites get into the body can also be answered, he thinks, by the following facts: By far the greater number of cases of tuberculosis take their origin in the respiratory tract, and the infectious material is first to be discovered in

the lungs or bronchial glands. It is therefore very probable that the tubercle bacillus is inhaled sticking to the particles of dust. Concerning the way in which they get into the air there cannot be much doubt when one considers what enormous masses of them are present in the cavities of the lungs of phthisical individuals and everywhere spread broadcast by the expectoration.

In order to obtain an idea of this the sputa from phthisical individuals was examined, and in about half of all the cases were not only abundant masses of the bacillus found but also those which carried spores. Inoculations with such sputa were as successful as if the material itself had been used. Even after drying for eight weeks this sputa was as virulent as ever. Therefore it can be easily imagined that the phthisical sputa dried upon clothing, floors, etc., can preserve its virulence for a long time, and when pulverized and inhaled can reproduce the disease.

Many questions must still remain for the future to decide, foremost among which is the part which hereditary tendency plays in the production of the disease, but to attempt to answer that now would take us too far into the realm of hypothesis. It is, however, a great step forward that in the future there will be something tangible to attack in the attempts to ward off the disease. The two points which come out strongly in this work of Koch's are the infectiousness of the sputa and the infectiousness of the disease of the household animals. And it is against these that attention should be first directed.

It is also to be hoped that the methods which have been proved successful in investigating the ætiology of tuberculosis may also be used in working out the other infectious processes, especially those diseases which are most closely related to it, as for example syphilis and glanders, and which form with it the group of the infectious tumors.

His paper is closed by the following significant paragraph:—

Let the physicians once recognize that tuberculosis is an exquisitely infectious disease, and the necessary precautions for its prevention will develop of themselves.

The presence of the bacillus in tuberculous nodules has been confirmed already by the independent discovery of the same by Baumgarten.<sup>1</sup> He has observed them in the nodules which were produced by the inoculation of pearly masses from cattle, and also in the fresh nodules from human lungs. His description of their form coincides with that given by Koch.

## Hospital Practice and Clinical Memoranda.

### CARNEY HOSPITAL.

SERVICE OF DR. M. H. RICHARDSON.

REPORTED BY C. W. SPARHAWK.

RENAL CALCULUS; REMOVAL; RECOVERY.

J. R., twenty-one years of age, single, farmer, was operated on at the Massachusetts General Hospital at the age of sixteen. The hospital records give the following history: Age sixteen. Has not been able to run or "ride in a cart" for a year, or to jump about without great pain. July 4, 1874, was examined by

Dr. Porter with a lithotrite in order to get the size of the stone. The calculus was phosphatic, and so soft that it could not be detached from the instrument. Dr. Porter was obliged, therefore, to crush it; it was about the size of two large peas. During the next day he passed a few fragments with his urine. The operation caused no pain nor after trouble of any kind.

July 7th, three days after the operation, he felt perfectly well, and was able to get about, jump, or run without any trouble or pain whatever. Since this time he has been subject to involuntary micturitions. His urine has contained "stringy settlements." He has frequently passed stones. Three years ago he had an abscess in the left lumbar region which lasted three months. When it broke a large stone escaped. As the swelling subsided he says he coughed up a large quantity of pus, first in gushes and then in small quantities. In September, 1880, he was taken sick again with pain in the left side. Passed light-colored urine of very offensive odor, containing much sediment. There appeared again a swelling in the left side as before, in the lumbar region. These symptoms continued till February, 1881, when, without medication, the urine became transparent. In February, while at Tewksbury, he had retention of urine for two days. At the end of this time he passed several small stones, which gave him complete relief. Has been aspirated twice, the last time at Tewksbury, yellow pus being drawn. He was admitted to the Carney Hospital in the latter part of June, 1881. At that time he was much emaciated; the skin had a very peculiar bronzed hue, suggesting the appearance described in Addison's disease; the tongue was coated; breath foul; temperature slightly elevated, and general appearance bad. A tumor was found in the left lumbar region, occupying the entire space between the crest of the ilium and the last rib. It was moderately soft, and deep fluctuation could be obtained.

June 26th. The tumor was aspirated, and about eight ounces of fetid pus was withdrawn.

July 5th. Analysis of urine: reaction acid; color pale yellow; specific gravity 1022; albumen one fourth per cent.; sediment considerable in amount, composed of pus and a few epithelial cells.

It having seemed advisable to make an incision for the sake of free evacuation and drainage, the patient was etherized, and an incision, three inches in length, made in a line parallel to the spine, and four inches from it. After evacuating about two ounces of fetid pus and exploring the cavity of the abscess, a small and hard concretion was found in the bottom of the wound. The walls of the cavity were smooth and velvety to the touch except where the calculus was attached. At these points it was necessary gently to separate the stone from the abscess wall. A moderate amount of hemorrhage followed, which was easily controlled. There was no escape of urine or anything suggesting it. The kidney could not be felt, nor anything resembling it, though the cavity of the abscess was sufficiently deep to enable the finger to reach the proper position of the viscus. Carbolyzed gauze was used to protect the wound, Lister's precautions having been carried out through the operation.

On renewing the dressing on the following morning, the patient having meanwhile passed a restless night, the gauze was found completely soaked with a most foul and stinking discharge. The odor of the wound was so very frequent that it was feared that the de-

<sup>1</sup> Centralblatt f. d. Med. Wissenschaft, April 13, 1882.

scending colon had been wounded during the operation, especially as the incision had been made very near the posterior wall of the intestine. Large oakum dressings were substituted for the gauze. During the next ten days the discharge became much diminished in quantity, and lost its fetid odor. The patient steadily improved in every way. An examination of the urine on the day after the operation gave the following results: amount in eight hours, one and one half pints; color high; specific gravity 1011; reaction alkaline; albumen one half per cent; sediment chiefly pus with some triple phosphates and renal epithelium.

The condition of the patient steadily improved during the ten weeks following that he remained in the hospital. The wound was well drained by means of a large drainage tube, which was removed from time to time as it became foul or in any way obstructed.

September 22d he was discharged for drunkenness. By that time he had gained thirty pounds in weight, was well filled out in the face and body. There was still existing a sinus which discharged more or less pus.

An examination of the calculus, made by Dr. Charles Harrington, proved it to be phosphatic. The weight was thirty grains, which is certainly very little considering its size.

## Reports of Societies.

### PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

#### SURGICAL SECTION.

H. C. HAVEN, M. D., SECRETARY.

APRIL 1, 1882. Dr. R. M. HODGES presiding. Fifty members present.

Dr. WILLIAM INGALLS reported a case (1) of

#### RENAL CALCULUS WITH RECOVERY AFTER OPERATION.<sup>1</sup>

Dr. M. H. RICHARDSON also reported a case (2) of the same nature.<sup>2</sup>

In the discussion which followed on the two cases, Dr. BLODGETT asked if the history of expectoration of pus in Case 2 was credited, and if so, was there supposed to be any connection between it and the condition found.

Dr. RICHARDSON answered in the negative.

Dr. BLODGETT also asked if the situation of the swelling was not unusual.

Dr. RICHARDSON stated that the patient was sent to the hospital as suffering from empyema. He had never credited the diagnosis, as there were no physical signs of it, and the operation was the result of a diagnosis of perinephritic abscess.

In reply to a question as to the nature of the discharge in Case 1, Dr. INGALLS said an analysis would shortly be made and published with the case.

Dr. LYMAN asked the theory of the origin of the abscess.

Dr. INGALLS thought that the blow had a causative effect, though there might have been other factors. He believed a blow was often the determining cause of many surgical affections, such as cancer of the breast; there were undoubtedly very often predisposing influences, but the blow was the directly exciting cause.

There were so many cases of cancer of the breast following a blow, or of disease of the knee-joint following a wrench or twist, that it seems unfair to deny a causal relation.

Dr. HODGES asked if there had been any severe hæmorrhage in either of the cases reported. The answers were negative. He then spoke of the great danger in these cases of introducing the finger into the cavity for explorations more than is absolutely necessary, on account of the net-work of vessels traversing the cavity, the supporting connective tissue of which had been destroyed. He also spoke of the interest of Dr. Ingalls' case, inasmuch as the operation was among the earlier ones of modern times. Although calculi were removed occasionally in ancient times, since the introduction of antiseptics "abdominal surgery" had so advanced that extirpation of the kidney and removal of a renus calculus are now comparatively frequent. In 1873, however, it was a rare operation. With the light of our present experience it is probable that in Dr. Ingalls' case, had it occurred within the last year or two, extirpation of the kidney would have been more strongly urged, especially in view of the fact that the first investigation of the tumor was made from the front.

Mr. Thornton has of late successfully removed the kidney from the front in two cases, and he states that this viscus can be reached through an incision on the outer edge of the rectus muscle more advantageously than by one in the median line.

Dr. LYMAN mentioned that Lawson Tait and Byford had also removed the kidney through an incision in front.

Dr. G. H. LYMAN read a paper entitled

#### A CASE OF PERINEPHRITIC ABSCESS.<sup>3</sup>

Dr. INGALLS asked the point where the aspirating needle was introduced.

The reader answered at the intersection of a line perpendicular to the anterior superior spinous process, with a transverse line on the level of the umbilicus.

In reply to a question as to the advisability of a free incision as soon as pus was proved to be present, Dr. LYMAN thought it unwise as long as the diagnosis was in doubt.

Dr. CUTLER did not consider it proved that the trouble in the bladder was not the cause of the perinephritic abscess, if such existed.

Dr. LYMAN answered that the cystitis was very mild, and it would be difficult to conceive of it as a cause. Interstitial nephritis may, as noticed by good observers, follow diphtheria; can interstitial nephritis cause suppuration?

Dr. LYMAN stated that the tumor was not aspirated in the rear for the reason that at first it bulged in one spot in front, and was more fluctuating there; later an incision and puncture were made farther back, as stated in the paper.

Dr. HODGES stated that he had always aspirated or opened from the rear because the drainage was better, and the peritoneum was avoided. In most of the cases he had observed the connection between the kidney and the abscess was absent; the abscess was perinephritic and not nephritic. It is a satisfactory class of cases to treat, as the relief is great and convalescence rapid. In regard to the question of empyema, it is well to remember that perinephritic abscess is often accom-

<sup>1</sup> Vide page 181 of the JOURNAL.

<sup>2</sup> Vide page 191 of the JOURNAL.

<sup>3</sup> Vide page 181 of the JOURNAL.

panied by a pleuritic cough, due to the irritation of the abscess pressing up against the diaphragm. In one case where he was called in consultation the patient had been supposed to be dying of phthisis; a perinephritic abscess was diagnosed and opened; during the operation the patient expectorated bloody pus, showing a connection between the lungs and the abscess; after the operation a discharging point on the inner side of the ankle was discovered, which proved to be the orifice of a sinus, the pus having burrowed from the lumbar region. The abscess might therefore be said to have extended the whole length of the patient's body.

DR. LYMAN asked if the case might not have been one of primary pleurisy resulting in empyema burrowing below the diaphragm.

DR. HODGES stated that although his memory failed to recall all the details, they were such as to leave no doubt in his mind at the time that the case was one of perinephritic abscess.

DR. GANNETT mentioned a case where the pus from the lumbar region had burrowed one third of the length of the femur.

DR. BLODGETT asked if the presence of fat globules in the urine afforded any indication.

DR. CUTLER said that the presence of free fat in large drops might indicate the rupture of any collection of disorganized tissue into some portion of the genito-urinary tract. Such an amount as Dr. Blodgett mentioned could only come from the disorganization of any tissue containing a large amount of fat, which is not the case in the kidney substance itself.

DR. MARCY spoke of a form of perinephritic abscess developing slowly, and convalescing slowly after operation.

DR. HODGES saw no difference between the cases reported by Dr. Marcy and other cases, except that the former did not get well as quickly.

DR. BRADFORD asked if the back had been examined to determine whether caries of the spine existed.

DR. LYMAN answered in the negative, and that there was nothing in the history of the case to call attention to the spine or to the possibility of the existence of caries, and, moreover, that he had supposed an abscess from caries would burrow along the course of the psoas muscle.

DR. BRADFORD stated that this was not invariably the case. In a patient for a long time at the Carney Hospital, a large abdominal abscess had existed for a long time, and caries of the spine was not at first suspected. The woman remained under observation for some time, and the later developments of the case, and the appearance of a projection in the lower dorsal region established the fact that caries of the vertebrae was present.

Pott's disease in the lower part of the spine is not easily recognized at an early stage, and the symptoms are not always such as readily attract attention.

## NEW YORK ACADEMY OF MEDICINE.

THE LATE DR. JAMES R. WOOD.

At the last meeting of the New York Academy of Medicine, held May 18th, the statistical secretary, Dr. F. V. White, made the formal announcement of the death of Dr. James R. Wood, and gave a brief biographical sketch of the distinguished surgeon. He was followed by Dr. Lewis A. Sayre, who made some eulogistic remarks upon Dr. Wood, and then presented a series of appropriate resolutions in regard to his death, which had been drawn up by Dr. Wm. H. Van Buren, who was prevented by illness from being present. In seconding the resolutions Dr. Willard Parker took the opportunity of paying a glowing tribute to the worth of the deceased, who was one of the original founders of the Academy, and Dr. Detmold also made a few remarks upon his many excellent qualities. Before putting the resolutions to vote the president, Dr. Barker, spoke eloquently of Dr. Wood, and alluded especially to the pertinency and force of the remarks which he had made the last time that he was present at the Academy, on the occasion of the reading of Dr. Sims' paper, in October last, on the contributions of gynecology to the subject of general peritoneal surgery. After the resolutions had been unanimously adopted, Dr. Barker announced that he would appoint Dr. Frederick L. Dennis, the pupil and intimate friend of the late Dr. Wood, to read an appropriate memoir of the deceased before the Academy in the coming autumn.

### LITHOTRITY WITH EVACUATION.

The principal business of the evening was the delivery of an address on the subject of lithotripsy with evacuation, by Prof. Henry J. Bigelow, of Boston, who was gracefully introduced by the chair. In commencing, Dr. Bigelow remarked that when asked, some time ago, by the president, to present this subject before the Academy, he felt that it was one which had already become so old and was so familiar to most surgeons that he could offer but little of interest in connection with it, and said that it was only when the request was again urged, at a subsequent time, that he had reluctantly consented to do so. He believed, however, that his own additional experience, and especially that of the New York surgeons, had now thrown more light upon the matter. He could not forget also that it was in New York that the procedure which he had labored to perfect had received its first distinct approbation, and that at a time when it needed friends. The profession here had then tested the matter by practical experiments, and he could not refrain from mentioning his special obligation, among others, to the distinguished Professor Van Buren for his interest and assistance in it.

The subject, he continued, was one relating distinctly to operative surgery, a mechanical one, and it was to the mechanical part of it — a mere matter of physics — that whatever advances had been made in lithotripsy of late were really due. He should confine himself, therefore, during the limited time at his disposal, to the mechanical procedure, because he believed that what the Academy would, perhaps, prefer now to discuss. There were a number of points in regard to which he would like to have an expression of opinion from some of the gentlemen present. Any common lithotrite, he went on to say, would break a stone, and most evacuator's will remove it. But it was an important ques-

I MUST go forth into the town,  
To visit beds of pain and death,  
Of restless limbs, and quivering breath,  
And sorrowing hearts and patient eyes  
That see, through tears, the sun go down,  
But never more shall see it rise,  
The poor in body and estate,  
The sick and the discolate,  
Must not on man's convenience wait.

— *The Golden Legend.*

tion which special instrument would do it best. Although it was stated, during the noted discussions which took place in London, in 1878, by Sir James Paget and other authorities that the subject of lithotomy had apparently gone as far as it could, and that the operation would probably not be further improved, yet since that time all the lithotritists had been steadily at work, and distinct advances had been made. It was desirable at the present day to use instruments materially different from those formerly in use, although the whole question was still one of breaking up a stone, and getting the fragments out through the urethra, an operation that had been in vogue for many years.

When Civiale commenced to operate he required from twenty to thirty minutes, but he gradually reduced the time as he improved his instruments to three or four minutes, a limit to the sitting generally accepted and taught since Civiale's day.

The means for removing the fragments completely, however, did not formerly exist. The sharp fragments remained in the bladder, and did the damage, not the operation. When it came to be possible to remove them, it was found, to the surprise of everybody, that the bladder was a very tolerant organ. That this tolerance of the bladder had never been suspected up to that time, and the fact that such an error had existed for half a century seemed to show the advantage of doubting everything in medicine of which we had had no personal experience. The single agent to which actual progress was due was the large catheter which held the urethra open while the fragments were drawn out through it, and it was a fact that the small catheter of Clover's instrument had retarded progress for a very long time. Long ago, in 1846, Sir Philip Crampton had drawn out a large quantity of dust in the form of powder by means of a vacuum made in glass. If fragments were completely pulverized, of course a small catheter would answer for the whole calculus, but the bladder could not afford to wait to accomplish this.

A large catheter by itself was not a new device, since it had been in use in former times to some extent. Collin's instrument had a catheter of number 25 or 26, but it was found to be inefficient, and was soon pronounced an impracticable failure. The distinctly new and important point in the instrument now employed was the use of a large catheter (of from 25 to 31) in combination with an efficient suction. This constituted the novelty of the thing. Having, then, the large catheter, the first question was, should it be straight or curved? This was a matter concerning simply the introduction of the instrument, and Dr. Bigelow said that he preferred a straight catheter, since he found it generally easier to pass this than a curved one. As most of the passage was practically straight, a straight tube could be introduced with greater facility than a curved one. The question of straight or curved was, then, simply one of convenience, and was related to the habit of the operator and sometimes to the individual case.

Dr. Bigelow next described the character of the extremity of the catheter which he preferred, and drew a diagram of it upon the black-board. It was oblique and blunted, and had a projecting lip of considerable length below, while the orifice was above. The orifice, he said, should be about the size of the calice of the interior of the tube; for if it were larger than this a fragment was liable to become lodged there, and in

this connection he mentioned a death that had occurred in consequence of the orifice of the catheter employed being disproportionately large. A fragment thus became fixed, and as a result of the laceration of the urethra occasioned by it the patient died of septicæmia. It was also recommended that the tube-wall, above the orifice, should be thickened, so that no injury might be inflicted by its edge.

The next point involved the important matter of retaining the fragments when they had been once gotten out from the bladder. It was a curious fact that until now all evacuator, so far as he knew, returned to the bladder something like from one third to one half of all fragments withdrawn. This had been attributed to the length of the elastic tube sometimes employed; but the length of the tube was not the main difficulty. As a fact, it was found on investigation that the fragments were really returned from the bulb, and that a little additional prolongation of the tube made very little difference. Nevertheless he had tried to devise a trap at the extremity of the tube. One consisted of a little glass cylinder containing a valve in the shape of a loose rubber ball, which worked backward and forward, and thus closed and opened the orifice alternately, while the water returned through a strainer. This device he had found to work very well, but as the objection had been made against it that it was too complicated an arrangement, he had afterwards employed a simpler one, which also acted perfectly, and which he had not as yet published. This was fastened more or less than a half an inch of cotton tube fastened at the end of the metal tube in such a way that it acted as a valve in closing and opening the orifice. Still, as even this might be thought by some surgeons a little complicated he had tried quite a variety of other valves. One objection to a metal valve was that it was liable to become obstructed by fragments. Consequently he had been obliged to resort to still other expedients, to which he would recur in a moment.

He would now go a step further, and speak of the evacuator as a whole. We are to dispose by means of it of air, water, and fragments. The receptacle for the fragments might be placed either between the catheter and the bulb or below the bulb itself. For his own part, Dr. Bigelow said, he considered it better to place the receptacle immediately below the bulb, especially for the reason that it materially shortened the instrument, and this of itself was a very important advantage. It was also an important matter to place the axis of the bulb in a line with the axis of the catheter. Otherwise there would be a leverage causing the instrument to work at great disadvantage. The moment the bulb and the receptacle were combined in one piece the question arose whether or not the catheter should be detached by an elastic tube to allow its freer motion. The ordinary straight elastic tube was liable to double on itself, and thus prevent the free flow of water; but a curved tube of proper construction was not open to this objection. In regard to the use of a stand, Dr. Bigelow said that his preferences had been in favor of it. Perhaps his present opinion might be best expressed in this way: If the stone were a small one, and the operation short, it was better to dispense with the stand; but if it were large, the stand was a considerable help, since the two or three pounds' weight of the instrument made quite a difference to the operator if it had to be supported by the hand. Still, the general belief in such matters was often the correct

one, and the prevailing practice, which was opposed to the use of the stand, he was willing to adopt.

Dr. Bigelow then exhibited the first instrument which he employed, and remarked, in connection with it, that it made no sort of difference at what point the catheter entered the bulb, provided it did not finally deliver directly at the top where the air collects. If the tube penetrated even for a short distance into the bulb, from above, an air chamber was formed by this means at once. The only air that belonged legitimately in the bulb was that which came from the catheter, and the amount of air varied with the capacity of the catheter. The best rule was to have the catheter deliver as near the centre of the bulb as possible, and when this was the case, the greatest possible facility was afforded for the uninterrupted passage of the fragments into the receptacle below. If the tube entered the lower narrow part of the bulb where the fragments accumulated, it was important that it should be prolonged above this point, or else they would be returned in great quantity to the bladder. This, he said, brought him to the point of showing how regurgitation of the fragments from the bulb took place in almost all instruments. He then exhibited one which he said had been abandoned by its author, beneath the bulb of which he had attached a short glass tube so that the course of the currents might be observed. It was clearly demonstrated that a considerable portion of the fragments went directly back into the bladder. How then, it might be asked, was evacuation ever accomplished by such an instrument? Simply by washing the fragments backward and forward between the bladder and the instrument until all of them had been finally dropped into the receptacle. This has been, till now, a serious defect of many evacuators. There is in this instrument also a current, which actually lifts the fragments out of the glass receptacle and sends them back to the bladder. In other words, the general fact held good, that wherever the water goes in an evacuator, the fragments go also, unless they are prevented by means of a strainer.

Dr. Bigelow next exhibited the latest instrument devised by Weiss, of London, which he had received during the past winter, and remarked that the first difficulty about it was that, as in Clover's evacuator, the bulb was not stiff enough. In his own instruments, a special point was made of having the bulb sufficiently stiff. A second difficulty was that the fragments, following as usual the course of the current, some of them collected in the bulb and were thence carried back into the bladder. Dr. Bigelow next exhibited another of his own instruments with a valve, which he had once published, and which worked perfectly well, although he said that it was not as simple in construction as was desirable. It was provided with a stand. He had often felt it a relief to stop once in a while in a long operation to see how things were going on, which the self-supporting character of the instrument enabled one to do with ease. With regard to the rubber hose which was attached to the top of the bulb and provided with a stop-cock, he regarded the device as a great advantage, and had continued to employ it in all his evacuators up to the present time. Its purpose was not only to dispose of the air, but especially to add or remove water. As had been stated, the only air legitimately held in the bulb was that contained in the catheter. If it were wished to get rid of even this amount of air, it could be promptly accomplished by compressing the bulb and filling its place with water by means of the hose. Another point in connection with

the latter was, that all bladders were not of the same size or the same elasticity. In a small bladder it was difficult to evacuate completely because the walls were liable to fall against the catheter. This was because there was not enough water in the bladder. It could be easily added by means of the hose; the quantity of water could be thus graduated exactly according to the desire of the operator. Sometimes during the operation the patient strained or vomited, so that everything became very tense; and in that case we had only to open both stop-cocks and deliver the water temporarily. He believed, therefore, that the hose was a valuable addition, both for the purpose of getting rid of air and of regulating the amount of water according to the circumstances arising from time to time during the operation.

Finally Dr. Bigelow exhibited the new and simple instrument which he said he had now settled down upon, and which could be used with either a single stop-cock or with two, as might be preferred. In the first place, it had a spherical bulb acting as a handle in the axis of the catheter. In the second place, it is quite short from end to end. In the third place, the obliquity of the tube carried the receptacle high in the air, one advantage of which was that it was nearer the level of the eye of the surgeon. In the fourth place, the whole thing fitted well into the cavity of the hand which held it. In regard to the use of stop-cocks, he preferred to have two instead of a single one. He then gave a demonstration of its manner of working, and, after a moment or two, it was found that there was not a fragment left remaining in the glass vessel used to represent the bladder. The simple method by which this desirable result was accomplished, he said, could readily be understood. There was a cylindrical strainer that prolonged the catheter inside the bulb, and inasmuch as all strainers may get clogged with fibrin, resulting from the inflamed state of the bladder, it was so arranged that it could be readily removed for the purpose of brushing it. It could be replaced in an instant; so that very little time was consumed in this way. The fragments enter the bulb from the bladder through the main orifice, by reason of the momentum which the current has acquired in coming from the bladder. But the combined area of the small apertures along the tube being much larger than that of the principal orifice at its extremity, most of the water returns by these apertures, and is strained.

Dr. Bigelow then spoke briefly in regard to the lithotrite. He stated that the most convenient instrument of any sort was that which was best adapted to the movements of the hand. In devising his own instrument, therefore, he had first considered which was the easiest motion of the latter, and had arrived at the conclusion that this was its rotation. He had, therefore, not only made the handle of a size adapted to that of the hand, but in such a way that it could be worked by rotation. He had also provided it with a lock by means of which any position of the blades could be maintained as long as desired; so that it was not necessary to change the position of the hand. The blades were made at as near a right angle as would admit of their introduction into the bladder with convenience and safety, and are thus found to work at a much greater advantage than the more oblique blades formerly sometimes employed. As the greatest impaction always took place at the heel of the instrument he had abandoned the idea of crushing much at this point, and passed a flange through it, in order to bisect the

detritus and discharge it laterally. The crushing was mainly done in front of the heel. When the patient was in good health, he said, in conclusion, he believed that the safety of the procedure depended simply upon the surgeon's skill, and that if proper care was observed there would very rarely be any bad results with the facilities now at our command. In cases where the kidneys were affected, however, the same favorable results were not, of course, always to be anticipated.

When he had finished his remarks the subject was discussed by Drs. Weir, Otis, Sands, Keyes, Gouley, Hamilton, Willard Parker and others, and a vote of thanks was then tendered Dr. Bigelow for the lucid and entertaining exposition of his methods with which he had favored the Academy.

### Recent Literature.

*Lectures on the Pathology and Treatment of Lateral and other Forms of Curvature of the Spine.* By WILLIAM ADAMS, F. R. C. S. Second edition. London: J. and A. Churchill. 1882.

When the first edition of this book appeared it easily won its place as the clearest and best work in the English language on the subject of lateral curvature. In the eighteen years which have elapsed since nothing has been written that is better. The slight additions which the writer has made in the second edition show, however, the little progress won in the knowledge and therapeutics of this subject.

Mr. Adams rejects the muscular theory of the causation of lateral curvature, that is, that which explains the distortion as the result of the contraction of certain muscles. He believes the deformity due to alterations in the articulations of the spinal column, resulting from abnormally distributed pressure, this latter resulting from "vicious" postures assumed habitually or from necessity by the patient. An interesting illustration of this has recently been mentioned by Ory: Two growing girls, sisters, attended the same school, and sat at the same bench during school hours. The seat and desk were apparently badly constructed, and did not give ample elbow room. The girls were in the habit of leaning on one arm, and to avoid crowding they leaned away from each other. The result was that a lateral curvature developed in each, but the curve was reversed in one as compared to that which existed in the other.

The points to which Mr. Adams alludes as useful for the ready recognition of the disease in its early stage should be remembered by all practitioners, namely, the prominence of a shoulder (that is, scapula); the prominence of the hip, and also sometimes of one breast rather than any curve in the line of the spinous processes. Rotation is to be seen most readily when the patient stoops. If no alteration of the articulations is present the spinous processes should come into line when the patient curves the back; in this position any undue prominence on one side as compared to the other can be seen.

Mr. Adams justly classifies the disease not on the direction and degree of the curvature alone, but also on the causative influences which give rise to the distortion. The classes he defines are as follows: First, cases essentially of constitutional origin, where the constitutional can largely predominate over the local.

Second, cases depending equally upon constitutional and local causes. Third, cases depending essentially on local causes.

Mr. Adams states his views in regard to treatment clearly and well. The appliances, however, which he figures illustrate the slow-rate progress in mechanical therapeutics during the last twenty years, as the "braces" remain nearly the same ungainly scaffolding which the past generation suffered under. It is to be hoped that the fertile American mind will develop some mechanical beauty in the "machines" of the past, or that at least writers will use more attractive wood-cuts.

The systems of treatment which have been recommended are, as grouped by Mr. Adams,—

First. The system of complete recumbency.

Second. The system of muscular exercises.

Third. The system of cutting spinal muscles.

Fourth. The system of mechanical extension.

Fifth. The system of mechanical support and pressure by the use of appliances.

Rejecting all "systems" as such, Mr. Adams claims superiority for the mechanical treatment if one plan alone must be adopted. He adds that it is impossible to straighten a curved spine in the manner that a bent knee is straightened, but in combination with partial recumbency, and, in some slight cases, with muscular exercises, it is quite possible to cure a curvature of the spine when slight and of recent formation in a young person, and it is certainly within our power most effectually to arrest the progress of curvature when more severe.

— At the annual meeting of the Worcester District Medical Society, May 10, the following officers were elected: President, Dr. E. B. Harvey, Westborough. Vice-President, Dr. Albert Wood, Worcester. Secretary, Dr. J. Bartlett Rich, Worcester. Treasurer, Dr. John O. Marble, Worcester. Librarian, Dr. Leonard Wheeler, Worcester. Orator, Dr. Warren Tyler, North Brookfield. Committee on Waldo and Wilder Funds, Dr. Thomas H. Gage, Worcester; Dr. John G. Park, Worcester; Dr. George E. Francis, Worcester. Commissioner on Trials, Dr. J. S. Ames, Holden. Councillors, Dr. E. B. Harvey, Westborough; Dr. Thomas H. Gage, Worcester; Dr. Oramel Martin, Worcester; Dr. J. Marcus Rice, Worcester; Dr. John G. Park, Worcester; Dr. Leonard Wheeler, Worcester; Dr. George E. Francis, Worcester; Dr. Frederick D. Brown, Webster; Dr. Ford Kendrick, Grafton; Dr. Franklin W. Brigham, Shrewsbury; Dr. Albert G. Blodgett, West Brookfield; Dr. Walter P. Bowers, Clinton; Dr. William M. Parker, Milford. Councilor on Nominations, Dr. Oramel Martin, Worcester. Censors, Dr. William H. Workman, Worcester; Dr. Wesley Davis, Worcester; Dr. George C. Webber, Milbury; Dr. Jerome Wilmarth, Upton; Dr. J. Bartlett Rich, Worcester. Auditing Committee, Dr. Joseph Sargent, Worcester; Dr. Oramel Martin, Worcester; Dr. Albert Wood, Worcester. Rice, New England Village; Dr. Henry S. Knight, Worcester. Reporter, Dr. H. M. Quinby, Worcester.

## Medical and Surgical Journal.

THURSDAY, MAY 25, 1832.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year including postage.*

*All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.*

HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

## SOME OF THE SANITARY FRIVOLITIES OF THE PRESENT MASSACHUSETTS LEGISLATURE.

It certainly is not a little distressing that the good people of the Commonwealth of Massachusetts should, at the present moment, be compelled to read the criticisms of a Matthew Arnold upon the social condition of this country at large, in which he insists, with a show of reasons not easily dealt with, that we represent essentially an immense middle class, with its virtues and limitations, divested of the social elevations and depressions of older countries on the other side of the Atlantic. It is, we say, not a little distressing that, at the very moment when, confessing the truth of some of these comments, we take refuge in the thought that the virtues of the middle class are those which perpetuate and develop, if they do not adorn, civic and social life,—that just at such a moment the legislature of Massachusetts, a State where education and good sense or hard headedness should, if anywhere, be known of their children, should indulge itself in silly eccentricities and inconsistencies far more characteristic of the follies of the "aristocrat" or of the ignorance of the "barbarian" than of the useful but unpicturesque middle-class social development.

The city of Boston at present discharges its sewage upon flats, which are bare at low water, and in the immediate vicinity of its densest population. This has been going on for years, and at times a nuisance results. The construction of the tunnel under Dorchester Bay, and of the outfall works on Moon Island, necessary for the discharge of the city sewage into the outer harbor, has been unavoidably delayed, and cannot be completed for two years. The legislature was petitioned to prevent the discharge of the city's sewage, pending the completion of the tunnel and outfall works, into Dorchester Bay, a project entertained for relieving the old flats, which have been thoroughly drenched in past years. A joint special committee of the two branches was appointed for a hearing on the subject. Some few representatives of the comparatively sparse population around the bay remonstrated; on the other hand, Mr. J. P. Davis, formerly city engineer, Mr. E. S. Philbrick, a civil sanitary engineer of well recognized capacity, Mr. W. H. Bradley, superintendent of sewers of Boston, Mr. E. C. Clarke, first assistant engineer in the construction of the new sewers, Dr. S. H. Durgin, city physician, and Dr.

Walcott, secretary of the Health Department of the State Board of Health, Lunacy, and Charity, all testified with the weight of their respective and varied trained skill and experience that the discharge of the sewage into Dorchester Bay for two years, pending the completion of the tunnel and outfall works, would greatly benefit the older parts of the city, and in no wise injure the districts around the bay.

The estimable joint committee after listening to such testimony took about as many minutes for deliberation as can be counted on the fingers of two hands, and then unanimously recommended that the city of Boston be restrained from discharging sewage at Old Harbor Point, Dorchester Bay.

Now the strangest part of it all is that this joint special committee represented a legislature which only a few weeks ago refused all legislation on the petition of the inhabitants of the town of Millbury for relief from the sewage of the city of Worcester discharged into the Blackstone River, on the ground that, though an offensive smell was shown to result therefrom, a nuisance had not been created, as it had not been proved that any one had been killed thereby. When the representatives of our middle-class virtues see fit to legislate in this fashion it is of little profit to rummage in the dictionary for adjectives,—an outlet to outraged intelligence which we leave to those of our readers who have a taste for it,—merely suggesting that they avoid such epithets as dishonest or ignorant, which are too vigorous for the kind of legislation, or pretense at it, we have been describing, and look rather among such words as trivial and frivolous for suitable characterizations.

If these same readers should wish further proof of the appropriateness of these words trivial and frivolous as applied to the dealings of this present legislature with matters pertaining to public health, they have simply to follow its action upon the bill for preventing the adulteration of food and drugs.

We have not heard any one accuse this legislature of being corrupt or wicked, but only of being very weak.

## FOURTH ANNUAL CONGRESS OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION.

THE Fourth Annual Congress of the American Laryngological Association will be held this year in the Hall of the Medical Library Association in this city, commencing Monday, June 12th, at ten o'clock A. M., and continuing during the following two days, June 13th and 14th, sessions being held each morning and afternoon. The committee of arrangements consists of Drs. Langmaid and E. W. Cushing. Dr. Langmaid will deliver the address of welcome.

The discussions will be stenographically reported and prepared for the press by Dr. Frank Woodbury, of Philadelphia.

The annual address will be delivered by the president of the Association, Dr. Frederick I. Knight, of this city. The following gentlemen have already signified their intention of presenting papers: Drs. Har-

rison Allen, Sajous, and Seiler, of Philadelphia, Daly, of Pittsburgh, Delavan, Elsborg, Jarvis, and Beverley Robinson, of New York, and Glasgow, of St. Louis.

The council of the Association has also selected the following subjects for discussion:—

(1.) The Singing Voice, its physiology, pathology, and treatment.

(2.) The Nature and Forms of Laryngeal Ulcer, specially the so-called Catarrhal Ulcer.

(3.) On the Utility or Non-Utility of Local Applications in Chronic Catarrhal Laryngitis.

(4.) Ozæna, its pathology and treatment.

The profession is cordially invited to attend the meetings, the programme of which we shall publish in a future number.

#### CULTIVATION OF CINCHONA IN THE UNITED STATES.

A COMMUNICATION, by Dr. George B. Loring, as Commissioner of Agriculture, was sent, on May 17th, to the United States House of Representatives relative to the cultivation of cinchona in the United States. His communication was in answer to a resolution of the House desiring information as to whether any portion of the United States was adapted to the growth of the cinchona, and he states "that the Department of Agriculture has, for the past sixteen years, annually distributed cinchona plants, some seasons to the amount of many hundreds, and that the reports received afford but little hope for success, except in Southern California, and, so far, no trustworthy experiments have been made in that region. Some of the species will live in Southern Florida, notably *cinchona succirubra*, which is one of the most robust, as also one of the most useful; but the climate of that State is not considered so promising for the establishment of an experimental plantation as the higher lands of Southern California." He quotes the reports of the Signal Office to make a favorable comparison as to temperature (monthly mean) between the climate of San Diego and that of St. Helena, where the cinchona flourishes, but calls attention to the importance of hygrometric observations in this connection as being of equal, if not greater, importance as regards vegetable growth, and this information seems at present to be lacking.

A correspondent of the Department, Willis Weaver, of Salem, Ohio, whose letter Dr. Loring furnishes in full, considers this tree as not strictly tropical, but belonging to the cold climate. "The cinchona belt begins at the limit of that of the orange, banana, coffee, ham-bone, etc." The whole cinchona region is liable to a variation of frost any night of the year, and considerable ice is formed in some parts of it. He considers that the plants in this country have been killed by heat rather than by cold, and that certainly few localities could be less congenial to this tree than the hot, flat, and water-soaked soil of Florida. The conclusion arrived at is that they are mountain plants, loving free air and alternate mist and sunshine, in a

warm, equable, and very moist atmosphere, at elevations where the mean yearly temperature indicates 64° Fahrenheit.

#### MEDICAL NOTES.

— Surgeon J. J. Woodward, of the United States Army, is reported to be seriously ill at Nice.

— The so-called "Brunelli process" of embalming is as follows: (1.) The circulatory system is cleansed by washing with cold water till it issues quite clear from the body. This may occupy from two to five hours. (2.) Alcohol is injected so as to abstract as much water as possible. This occupies about a quarter of an hour. (3.) Ether is then injected to abstract the fatty matter. This occupies from two to ten hours. (4.) A strong solution of tannin is then injected. This occupies for imbibition two to ten hours. (5.) The body is then dried in a current of warm air passed over heated chloride of calcium. This may occupy two to five hours. The body is thus perfectly preserved, and resists decay. The Italians exhibit specimens which are as hard as stone, retain the shape perfectly, and are equal to the best wax models. It will be observed in this process that those substances most prone to decay are removed, and the remaining portions are converted by the tannin into a substance resembling leather.

— At a recent meeting of a medical society in London, in a discussion on lead palsy, one member related the case of a lady who suffered severely from that affection after using a hair wash for two years, her wrists being particularly affected. Her cousin, who had used the same wash for a similar length of time, also suffered from distinct symptoms of lead palsy. A second member had observed three cases of the form of insanity produced by chronic lead-poisoning in persons who had used hair wash; and a third related his experience of two instances of lead colic traced to the same cause.

— At the primary or anatomical and physiological examination for the membership of the Royal College of Surgeons of England, sixteen hundred and nineteen students from the various metropolitan and provincial medical schools have, so far, presented themselves. This is an increase of seventy-six over the number at a corresponding period of last year.

#### NEW YORK.

— An interesting local outbreak of typhus has lately been reported. On the 3d of May the Sanitary Bureau received notice of a case of typhoid fever in a tenement house on East Forty-Seventh Street, and when the inspectors visited the premises it was found that the patient was suffering from typhus fever, and that there were no less than nine other cases of the same disease in the house. Of the ten cases, two were dying, four were seriously ill, one was just coming down with the fever, and three were convalescing. Three of the patients were at once removed to the Riverside Hospital on Blackwell's Island, and the two

worst cases (which were allowed to remain on the premises) died during the night. By the evening of the 4th another new case had developed, and this patient, together with one of those previously attacked, was removed to the island early on the morning of the following day. The adjoining house was then visited, and two cases of typhus fever were found on the top floor. One of the patients had had it for three weeks, the attack coming on a fortnight after he had visited one of the families whose members were ill in the next house. He was convalescing, but very weak, and was allowed to remain where he was; but the other patient, a woman, was removed to the hospital. At this dwelling the authorities learned that the owner of the property, named Fogarty, had been taken sick about the same time as the first of these patients, and that he, too, had visited the family next door. Mr. Fogarty was then visited at his own residence, and was found to be convalescent. No new cases occurred on the 6th, but on the 7th a daughter of a grocer living on the ground-floor of the house adjoining the one in which the two cases were discovered was reported ill with the fever. It was ascertained that two families had removed from this house on the 1st of May. On the morning of the 8th, the sanitary inspector who had had the oversight of the above cases was notified to see a dead case at the Presbyterian Hospital, and on visiting the institution found that it was a woman belonging to one of these families. She had been received at the hospital on the 4th of May in an unconscious condition, supposed to be due to injury, and had died without recovering consciousness on the 5th. The autopsy showed that she had died of typhus fever. The first case originated on the 30th of March, in the first of the three houses, and it was thus five weeks before the attention of the health authorities was called to the existence of the disease. Sixteen persons in all contracted the fever, three of whom died; while the remainder are either convalescent or doing well. Of course the houses have been thoroughly disinfected and fumigated, and are still closely watched.

— Small-pox, which for some time had prevailed to very slight extent, has lately been somewhat on the increase, and a number of cases concealed in tenement houses have been discovered. Between eight and nine on the evening of May 2d, an unmarried woman, living alone, died of hemorrhagic small-pox in the hall way of a crowded house on Hudson Street. Notwithstanding her condition, she had actually been out to a neighboring saloon to get a drink of liquor, and before reaching her room on her return fell dead in the hall, where, through some oversight of the authorities, her body was allowed to remain, to the imminent danger of the other occupants of the tenement, until nine the next morning. When the sanitary inspector visited the premises he at once recognized the body as that of a woman whom he had seen just two weeks before in a house where there was small-pox, and who had obstinately refused to be vaccinated, although strongly urged to do so.

— The seventy-fifth annual Commencement of the College of Physicians and Surgeons was held at

Steinway Hall, on the afternoon of Tuesday, May 16th, when degrees were conferred by Dr. Alonzo Clark, president of the college, upon one hundred and fifteen graduates. The address to the class was made by Luther R. Marsh, Esq. Prof. John G. Curtis, secretary of the Faculty, read the award of the usual prizes to students, and Prof. Wm. H. Draper, president of the Alumni Association, announced that, owing to the lack of original investigation on the part of the writers, no prizes had been awarded to any of the essays submitted in competition for the Alumni Association Prize of \$500, the Stevens Triennial Prize of \$200, or the Joseph Mather Smith Prize of \$100, open to the Alumni of the College, or for the Cartwright Prize of \$500, open to universal competition.

On the evening of May 17th the annual dinner of the Alumni Association was given at the Hotel Brunswick, and among the invited guests were Prof. Henry J. Bigelow, of Boston, the Rev. Robert Collyer, D. D., and Dr. Fordyce Barker.

#### WASHINGTON.

— The Medical Association of Washington D. C., at a meeting held May 13th, adopted the following:—

*Whereas*, The Medical Society of the State of New York has so modified the rules controlling its members as to permit of consultation with irregular practitioners of medicine.

*Resolved*, That this Association expresses its unqualified disapproval of the course thus taken, regarding it as detrimental to the progress of medical science, degrading to the dignity of the profession, and opposed to the best interests of the public.

*Resolved*, That the science of medicine admits of no sects or schools; its object is the rational study and treatment of disease. Medical knowledge is gained and applied by the same methods as in other departments of science, and the recognition of systems of practice which are committed to any exclusive dogma or whose adherents assume designations implying the adoption of special modes of treatment, is inconsistent with the pursuit of medicine as a science and with the honest and honorable practice of our art.

— The Toner collection of books is likely at last to find a permanent resting place which shall perpetuate its collector's name. This collection is stated to be "a large and valuable collection of books on medical science and historical and miscellaneous subjects," and the United States House of Representatives on May 15th, passed a resolution accepting it as a donation to be placed in the National Library of the United States, to be there set apart as the Toner collection, to be appropriately and distinctively bound and catalogued, and the donor to be allowed to make additions to the collection from time to time as he may desire, and to have liberty to insure the perpetual increase of the collection by the establishment of a trust fund for the purpose. The resolution makes the collection to consist of about twenty thousand volumes, or upward, in number; to which the donor has devoted considerable funds and a large part of his life.

## Miscellany.

## SOME OF THE HEALTH RESORTS OF THE SOUTHWEST.

BY ALBERT N. BLODGETT, M. D.

DURING a recent trip through portions of Kansas, Colorado, and New Mexico, a visit was paid to the various springs and health resorts of this section of country, and some facts were learned in relation to their efficacy as healing agents in disease, as well as to the climatic influences of these regions upon the diseases incident to littoral districts and low altitudes. The facts regarding the localities visited were obtained not only from the residents of the several places, who might be supposed to entertain a certain amount of prejudice in favor of each individual resort, but from those who had repaired to the several places on account of ill health and who narrated their personal experience, and also from physicians of intelligence and candor, who may be considered tolerably accurate judges of the influence of the country upon constitutional diseases. The native populations of each locality were found to be singularly free from all affections of a catarrhal or exudative character, and the prevailing diseases, so far as ascertained among the original dwellers of the several districts, are principally the exanthematic fevers, and the contagiosa, with a certain sprinkling of pneumonia; while the hospital service, as ascertained by personal inspection through the courtesy of the attending physicians, is confined chiefly to surgical injuries, generally cuts and fractures, and the milder febrile and other constitutional diseases. Small-pox is thought to be endemic among the native population, and is treated by seclusion and otherwise much as with us, but I should judge with a lesser mortality. I was unable to learn the prevailing causes of death among the Indian and Mexican residents, no one knowing, or apparently caring, enough about vital statistics to ascertain these important facts: the reply universally given to questions upon this point was "they dry up and blow away." In connection with this statement it is an interesting fact that in a somewhat extended tour I saw not one of the natives who seemed sick, though many were observed so decrepit and wrinkled by extreme age, that the assertion as to their ultimate fate seemed no great improbability. The only case of death occurred to a child in a Mexican family, at Santa Fé, and was thought to have been caused by small-pox; the funeral, however, took place in the usual public manner, the body being borne through the streets by the friends, without a coffin or other sepulchral investment. The Governor of New Mexico, whose guest I chanced to be at the time, remarked that this was the second native funeral he had seen during his residence, of many months in that city, thus indicating a rarity of that event, which is certainly unknown in our vicinity.

The entire section of country visited consists of a high, level, or rolling plateau of an average elevation of from six to seven thousand feet above the level of the sea. The atmosphere is everywhere remarkably clear, the air is very dry, clouds are seldom visible, and rarely obscure the sun; rain scarcely falls except during the short wet season, and is not then accompanied by the same depressing effects as to sensitive constitutions as is common near the sea-coast. Breathing is accompanied by a peculiar exhilarating effect, and

a pleasant sensation, which I think is universally experienced by persons accustomed to a lower altitude, which incites the effort to deep inspiration, and a more complete expansion of the chest. A moderate degree of activity is not uncomfortable, though violent exercise soon causes a panting respiration owing to the rarity of the atmosphere, but is not associated with feelings of bodily fatigue. The appetite is generally keen, the assimilation is improved, sleep is easy and refreshing, and all the natural functions of the body seem to be invigorated.

The first place which was visited was the Hot Springs at Las Vegas in New Mexico, situated near the mouth of a romantic cañon, at an elevation of 6400 feet above the level of the sea. Here a stay of several days was made. This section of country forms a part of the southern border of the great central elevated plateau which extends along the eastern base of the Rocky Mountains through Colorado and the northern half of New Mexico. The springs are about six miles from the city, and are the ancient, Los Ojos Calientes of the natives, who have long entertained a high regard for the curative properties of these waters, which are known to every tribe and nation in the Rocky Mountain region. They are twenty-two in number, and range in temperature from 115° to 145° F. They are situated within the compass of a few feet of each other, some of them boiling up immediately from the bed of the Rio Gallinos. The volume of water which issues from the principal outlet is estimated at about one and a half gallons per minute. All the springs show more or less of a calcareous deposit about their basins, but none, so far as was observed, are sparkling waters. They are all alkaline, the chief chemical ingredients being the carbonates, sulphates, and chlorides of the various alkaline bases. In medicinal properties they much resemble the celebrated thermal springs of Arkansas, to which they must prove formidable rivals. They are preferable to the latter springs in respect to their higher elevation, purer atmosphere, and absence of malarial infection.

The arrangements for the reception and care of visitors to this resort are admirable. A railway has been constructed from the city of Las Vegas to the very threshold of the hotels, to which a broad bridge from the railway station forms the entrance. Two hotels, built upon the very banks of the river, and situated only a few rods from the baths or from each other, furnish an aggregate of about five hundred rooms for guests. The buildings are surrounded by broad, covered verandas, and are so planned that the sunshine enters every room, thus adding materially to the cheerfulness of the place and to the comfort of its occupants. The larger of these hotels was opened the present season, and is furnished with a degree of comfort and luxury which is an agreeable surprise to the weary pilgrim traveling from afar.

The halls and corridors are wide and lofty, and are carpeted throughout with heavy crimson Axminster fabric; fire-plugs, with hose attached, are located at three points in each corridor on the several floors, although there is no fire in the building. The house is heated by steam generated in boilers situated in a separate building, and lighted by gas manufactured on the premises. Electric bells from each room communicate with the office. The dining-hall is very large and pleasant, the table excellent, and the service throughout unexceptionable. The water-closets are of the most ap-

proved models, the water supply constant and abundant, and the sanitary arrangements apparently perfect. The water for household purposes is derived from a reservoir situated at an elevation of several hundred feet above the hotel, and conveyed thither in three-inch cast-iron pipes. The sewage is conducted in large pipes to a considerable distance from the hotel, where it is discharged into the current of the river.

The facilities for baths are very complete. A bath-house, two stories high and built of stone, two hundred by forty-two feet, stands near the principal hotel, with which it is connected by a graceful span bridge. Here six hundred guests can be accommodated in a day with douche, spray, tub, and vapor baths, and the house also contains shampooing and cooling rooms, comfortable dressing and waiting rooms. In addition to these, hot mud baths are given, and the presence of earth as mud is thought to add materially to the efficacy of the bath in the treatment of rheumatic and neuralgic cases.

Thirty miles away as the crow flies, but seventy-five miles by rail over the high Glorietta pass, lies the city of Santa Fé, said to be the most ancient town in the United States, and the central point of a large district full of interest to the student of natural history, and valuable in the study of prehistoric civilizations on this continent, and the evolution of the present native peoples. Not far away is the pueblo of Taos, celebrated for its mediæval pottery, which is still fashioned and made in the ways peculiar to the mound-builders and other peoples who once lived in various portions of the central part of the United States, but have long since become extinct, leaving colossal mounds and the contained relics as the only record of their existence. Here the Indians are said to still religiously maintain the sacred fire kindled by their deified Montezuma centuries ago at the time of his transfiguration and ascension at Pecos, some miles away. At the latter place may be seen extensive ruins of places of worship erected by his followers. In the neighborhood of Santa Fé is also the secluded pueblo of the Zuni Indians, some of whom have recently awakened much public interest during their visit to the Atlantic sea-board. In various directions are the descendants of still other tribes of ancient peoples, to whom a visit must be a source of pleasure and instruction.

The city of Santa Fé is located on the incline of a high sloping table-land, having a general direction toward the southeast, and draining its waters into the Rio Grande River. The elevation is very nearly the same as at Las Vegas, and the climatic conditions are similar, excepting that the absence of near mountains and forests makes the atmosphere less exhilarating, and the heat is somewhat oppressive. The objects of interest in the town itself are soon exhausted, and unless the visitor can make excursions into the neighboring country the place must soon become wearisome. There are but few public buildings, no desirable places of entertainment, and the best hotel, although very clean and comfortable, is not a place for prolonged residence, as the table is very ordinary and not adapted to the capricious tastes of an invalid. The water-supply is uncertain, if the observations of a few days may be assumed to be correct, and drainage is unknown. I was told that the sewage is retained in vaults and allowed to percolate into the soil. The extreme dryness of the atmosphere prevents decomposition to an extraordinary degree, so that offensive odors were not

noticeable, even when unsanitary objects met the eye. The house-drainage flows through the streets in shallow open gutters, and, finally, that which is not absorbed or evaporated finds its way into the "river," which at the time of our visit was a modest rivulet two or three inches in depth, passable at any point dry-shod by means of the pebbles of its bed. The houses are, with a few recent exceptions, of adobe construction and seem very comfortable.

There is an air of business and enterprise observable in the streets which seems strangely incongruous with the surroundings. From an elevation just outside the town not a human habitation could be seen in any direction in the surrounding country, so isolated is the location of the city and so contracted its boundaries. In five minutes, from any part of the city, one is upon the open table-land.

Passing northward to Colorado the first accessible stopping place is Pueblo, the key to the intricate railroad system of this flourishing State. The growth of this town in the last few years has been something phenomenal, and borders on the marvelous. In no other part of the State perhaps are there such evidences of activity in all the industries pertaining to mining and the products of mining. Poundries, forges, mills, smelting and other large establishments, are crowded together, and the city has far outgrown the expectations of its most sanguine friends.

Fifty miles further by rail, at the foot of Pike's Peak, is Colorado Springs. This is a most delightful place, situated at the very edge of a level prairie where the action of water has furrowed out a broad shallow valley, in which a small stream finds its way southward to empty into the Arkansas River. The village is regularly laid out in broad streets at right angles, there are fine parks and trees, the buildings are attractive and tidily kept, and there is a total absence of any objectionable features. Thrift and industry are everywhere apparent, and a spirit of public enterprise is plainly noticeable. The greater number of the inhabitants are those who in former times repaired thither as invalids, but have received such benefit from a residence there that they have made the place their permanent abode, often engaging again in the same business which they had formerly been obliged to renounce. This place seems to be admirably adapted for cases of pulmonary disease. Many persons now in apparently good health describe their condition as having been very critical on their arrival, but under the uniform temperature of the region, the constant sunshine, the absence of dew or fog, the pure air, the high elevation, and the rarer atmosphere, they have almost invariably been restored to their previous health. Only one person was encountered who did not show marked improvement, but this was a case of phthisis so advanced a stage that recovery was entirely out of the question, and the patient should never have been allowed to leave his home. Death was evidently imminent at the time of his arrival.

Six miles from the village is Manitou with its beautiful private residences and large summer hotels. The springs are some six or eight in number, and are scattered over a considerable area. They are chiefly alkaline, the sulphates of magnesia and potassium being present in unusually large amounts. Free carbonic acid gas is constantly escaping in large volumes. The waters are all sparkling and very pleasant, and exert a mild laxative and diuretic action, which is said to

gradually induce a marked alterative effect in the general system. Nearer the base of the overhanging peak is a strongly ferruginous spring, said to be a powerful tonic, which is doubtless true, as its taste is very similar to that of dialyzed iron, and two competent chemists who were present assured me that the metal was contained in the water in remarkable quantities.

Of all the places visited Colorado Springs would seem to be the one combining more of the beneficial qualities of a sanitarium with the minimum of objections. It has good society, churches, opera, beautiful drives, hunting, mountain climbing, constant sunshine for months in succession, a dry atmosphere without dew or night dampness, a gentle, invigorating breeze almost continuously, and magnificent scenery in the immediate neighborhood. No better location could be chosen for study in certain departments of geology or natural history, and the region abounds in extensive and romantic views. Added to all these is the important factor that several skilled physicians from the eastern States reside here, having "come to cough but remained to practice," so that competent medical advice is always obtainable in case of sickness.

#### SIXTH ANNUAL REPORT OF THE JOHNS HOPKINS UNIVERSITY.

We have received the Sixth Annual Report of the Johns Hopkins University. The work during the year seems to have gone on quietly and successfully. We understand that necessary improvements and developments have absorbed the entire income of the university this last year, whereas the year before about \$60,000 was added to the principal. The president reports that the number of associates has been increased by the appointment in Biology, of Henry Sewall, Ph. D., formerly an assistant there, and recently a student in the University of Leipzig; in Sanskrit, of Maurice Bloomfield, Ph. D., who continued the study of Comparative Philology at Leipzig and Berlin after graduating there two years ago; in Mathematics, of Thomas Craig, Ph. D., who has been connected with the university since its opening and has also, of late, been an adjunct of the United States Coast and Geodetic Survey; in Biology, of William T. Sedgwick, Ph. D., and in English, of Henry Wood, Ph. D. (Leipzig), recently one of the teachers in the Friends' School, Providence.

#### THE VETO BY THE GOVERNOR OF MASSACHUSETTS OF A BILL TO REGULATE THE PRACTICE OF DENTISTRY.

The following is the text of the veto by the Governor of Massachusetts of a bill to regulate the practice of dentistry in the State:—

*To the Honorable Senate:* I herewith return to the senate, in which it originated, a bill to regulate the practice of dentistry, with my objections there to.

A controlling objection is, that by force of it the whole system of dentistry is made a possible monopoly in the control of a few corporations with restrictive by-laws, consisting of less than a hundred members, most of whom are in Boston, while the whole number of dentists in the Commonwealth is reported to be about one thousand. Under this act no person could hereafter enter the practice of dentistry except by consent of the corporation, which is put under no obligation to examine or accept of any person, nor would it may examine whom it pleases, and none

else. It may set any standard it sees fit. The diploma of any other dental or medical society is nothing, unless such society is "recognized" as "respectable" by the Massachusetts Dental Society. But there is no standard of such respectability or means of compelling such recognition. How and when is an applicant in Nantucket or Berkshire to get into the profession? Suppose the society fall into the hands of those who desire no more competition. Grant, as is true, that the purpose of the bill is well meant and that the Massachusetts Dental Society would of course have no other purpose than to keep the profession clear of impostors; nevertheless a wrong principle is involved, and the precedent is bad. If there must be a certificate of qualification, let it come from a board required to sit at stated times and in convenient places throughout the State and to pass upon the qualifications of all who apply. Such a board, too, should spring from a broader basis than a single society, however worthy. This would obviate the special objection to the present bill. I am persuaded the bill should be more carefully drawn before it becomes a law. It is not easy to see why there should be special legislation concerning dentists only. Why not concerning apothecaries, physicians, oculists, aurists, surgeons, cooks, plumbers, and the other businesses which involve life and health? It would perhaps be better worth while to consider the expediency of a general statute to the effect that any person pursuing a business or profession without sufficient skill therein shall be punished. Such a statute in the hands of judge and jury would never work injustice, and yet would be ample for those exceptional cases of imposition, on the strength of which various special statutes are urged from year to year.

JOHN D. LONG.

#### COMBINED AND SEPARATE SYSTEMS OF SEWERAGE.

In discussing the relative advantages of the combined and separate [such as that at Memphis] systems of sewerage, Mr. Eliot C. Clarke arrived at the following conclusions in a paper published in the Report for 1880 of the Massachusetts Board of Health, Lunacy, and Charity:—

"The result of this discussion appears to show that a separate system of sewerage is only necessary where cellars are so low that they must be drained by pumping; that in other cases its only merit is its cheapness; that the saving in first cost of sewers will be about three fifths, depending on the character of the soil; that the final economy will depend on circumstances; that the system would only be advisable where the branch sewers could incline not much less than one in one hundred; that surface drainage for rain is attended by a varying amount of inconvenience and damage, which increases with the growth of a town."

These conclusions Mr. Geo. E. Waring, Jr., in a paper contributed to the *American Architect*, states would, according to his experience, be more correctly given thus:—

"The result of this discussion appears to show that a separate system of sewerage is *necessary* where cellars are so low that they must be drained by pumping, and where the cost of a combined system cannot be afforded; that its economy is always very great; that it is entirely efficient with a fall of one in five hundred; that surface drainage can be prevented from causing inconvenience or damage worth considering, no matter what the size of the town, for an outlay, which, compared with the extra cost of a system of combined sewers, would be trifling; and last and most important, that while combined sewers cannot possibly meet the necessary sanitary requirements, separate sewers can be made absolutely safe, affording the only means now known for the perfect sanitary drainage of a town of any size, and that for these reasons the separate system is always advisable."

## REPORTED MORTALITY FOR THE WEEK ENDING MAY 13, 1882.

#### DEATH: JAMES MORISON, M. D.

JAMES MORISON, M. D., died at his residence in Quincy on Saturday morning May 20th. He was born in Peterborough, N. H., June 20, 1818, graduated at Harvard University in 1844, and received his medical degree from the University of Maryland in 1846. He was nearly five years resident physician of the Baltimore Infirmary. From 1850 to 1867 he practiced his profession in San Francisco, with the exception of about two years spent in Paris attending medical lectures and the clinics of the hospitals. In addition to an extensive medical practice, he assisted in the organization of the first medical school on the Pacific coast, and for five years filled the office of professor of the theory and practice of medicine and pathology in that school. He was one of the trustees of the University of the Pacific and vice president of the California Medical Society. He left California in 1867, and in June, 1869, removed to Quincy, where he has practiced his profession for thirteen years. He had just been chosen president of the Norfolk District Medical Society, to which he belonged.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MAY 13, 1882, TO MAY 19, 1882.

LIEUT. COLONEL GLOVER PERIN, surgeon, Major WILLIAM C. SPENCER, surgeon, and Captain PHILIP F. HARVEY, assistant surgeon, directed to represent the Medical Department of the Army at the annual meeting of the American Medical Association, to be held in St. Paul, Minn., on June 6, 1882. S. O. 114, A. G. O., May 17, 1882.

MAJORS C. T. ALANVANDER and J. H. JANESWAY, surgeons, and Captain R. H. WHITE, assistant surgeon, detailed as members of a board of medical officers to examine into physical qualifications of members of the graduating class, and of candidates for admission to Military Academy. S. O. 110, A. G. O., May 12, 1882.

LIEUT. W. R., captain and assistant surgeon. Assigned to duty at Fort Bliss, Texas. S. O. 95, Department of the Missouri, May 8, 1882.

MASSACHUSETTS MEDICAL SOCIETY. — One hundred and first anniversary. Boston, June 13 and 14, 1882. Programme for the day, June 13, 1882. Twelve o'clock, m. Meeting in Horticultural (upper) Hall, 109 Tremont Street, Boston, to hear papers read as follows: (1) Cottage Hospitals, by Lucius W. Baker, M. D., of Baldwinville. (2) Disease Germs, by James W. Henshaw, M. D., of Ludlow. (3) The Compendium of Anal Fistula and Pithia: a Clinical and Pathological Investigation, by Walter Eli, M. D., of Cambridge. (4) Obscure Menstrual Symptoms of Disease, by Charles F. Tolson, M. D., of Boston. Appointment at two o'clock. Four o'clock, p. m. An address (under 102 of the Society) will be held for the transaction of business. Dinner, Tuesday and the morning of Wednesday, June 14, 1882, an exhibit of surgical appliances in lower Horticultural Hall. Programme for Wednesday, June 14, 1882.

Nine o'clock a. m., the one hundred and first annual meeting of the Society will be held in Horticultural Hall, Boston. (5) American Dyspepsia, by James H. Robbins, M. D., of Hingham. (6) A Study of the Action of Iron, by Francis H. Williams, M. D., of Boston. (7) Relation of Mould Fungi to Disease, by William W. Gannett, M. D., of Boston. Twelve o'clock m. precisely, the annual discourse, by James P. Lynde, M. D., of Athol. The hall doors will be closed at twelve o'clock precisely, and will remain closed during the delivery of the discourse. One o'clock p. m., the annual dinner will be served in Music Hall.

GEORGE S. OSBORNE, M. D., Anniversary Chairman.

No person will be admitted to the dinner without a ticket. The dinner ticket (not transferable) may be obtained on Tuesday and Wednesday, in lower Horticultural Hall, on presentation of evidence that the dues for the current year have been paid.

Councilors' meeting. The annual meeting of the Councilors will be held at the Medical Library, No. 19 Boylston Place, Boston, on Tuesday, June 13, 1882, at seven p. m. precisely.

Censors' meeting. The Censors for Suffolk District, officiating also for the State Society, will meet for the examination of candidates for fellowship, on Thursday, June 8, 1882, but they cannot examine any candidate who is already a resident, or in practice, in any district other than Suffolk.

THE SECTION FOR CLINICAL MEDICINE AND PATHOLOGY OF THE SUFFOLK DISTRICT MEDICAL SOCIETY will meet at 19 Boylston Place, on Saturday, May 27th, at 7.45 o'clock. The following subjects will be presented: Ernest W. Bowditch, Esq., Sanitary Engineer, The Sanitary Aspect of Nahant, Mass. Dr. S. H. Dargatz, chairman of the Boston Board of Health, The Sanitary Work of the City Board of Health. Dr. J. H. McCollum, city physician, The Small-Pox Epidemic in Boston. Dr. Alfred B. Heath, port physician, The Work at Quarantine. His honor, the mayor, Dr. S. A. Green, is expected to be present. This is the final meeting for this year.

ALBERT N. BLODGETT, Secretary.

BOOKS AND PAMPHLETS RECEIVED. — Medical and Surgical Reports of the City Hospital of the City of Boston. Third Series. Edited by David W. Cheever, M. D., Oliver F. Wadsworth, M. D., and A. L. Mason, M. D. Boston: Published by the Trustees. 1882.

Observations on Filaria Sanguinis Hominis in South Formosa. By W. Wykelan Myers, M. B., Surgeon to David Manson Memorial Hospital. Shanghai: Printed at the Statistical Department of the Inspectorate General of Customs. 1881. (For private circulation.)

Carotid Compression and Brain Rest. By J. Leonard Cornig, M. D., Member of the New York Neurological Society, etc. New York: Anson D. F. Randolph & Co.

Paul Broca and the French School of Anthropology. A Lecture delivered in the National Museum, Washington, D. C., April 15, 1882. By Robert Fletcher, M. D. Published and sold by Judd & Berwick.

Twenty Fourth Annual Report of the Washingtonian Home, located at 41 Waltham Street, Boston.

## Lectures.

### MEDICAL HIGHWAYS AND BY-WAYS.

A LECTURE DELIVERED BEFORE THE STUDENTS OF THE MEDICAL DEPARTMENT OF HARVARD UNIVERSITY, MAY 10, 1882.

BY OLIVER WENDELL HOLMES, M. D., LL. D.,

*Parkman Professor of Anatomy.*

I PROPOSE to point out some of the stepping-stones and some of the stumbling-blocks which have helped or hindered the progress of the Art of Healing. When I look at the long array of the volumes of Sprengel; when I remember the stores of learning contained in the eight quartos of Haller's *Bibliotheca*; when I notice the space occupied by the condensed accounts of Bostock and Alison, all now antiquated and constituting a mere prelude to the medical history of the last generation, I smile to think of the task before me and the scanty hour allotted for its performance. Evidently I have little time to waste in the way of introduction.

But in looking back over the past history of medical science and art we find the prospect like that of the forest settler with a burnt district behind him. Here and there a tree may be standing, but the eye ranges over charred and lifeless trunks with their feet in the ashes of their leafy raiment. Why should we linger among the blackened stumps and the desolate scenery?

Everywhere the stumps of old theories, the ashes of futile experience, fill the landscape, and we feel tempted to turn away from a view so barren and hopeless. Yet we must remember that these wrecks of old beliefs have in their time furnished shelter and shade to the generations that knew them living. We must not forget that they ripened the seeds of growths yet vigorous with deeper roots and stronger branches. But still we shall find a few rapid glances over the burnt district of the past enough for our purpose.

There must have been a time when human beings had nothing but their instincts to guide them to the means of relief when suffering from accident or disease. Animals know enough to rest an injured part and to lick their wounds. An idiot girl, mentioned by Dr. Carpenter, gnawed the umbilical cord to separate herself from her new-born child. There is a popular notion that instinct directs some animals to the natural antidotes of poisons. But instinct in the human race is so soon replaced by experience that a very brief chapter disposes of it. It is enough to say that it is a guide always to be listened to and sometimes to be trusted. Cold drinks and cold affusion have often been asked for, and proved useful to the patient who longed for them. But a draught of cold water has frequently caused sudden death. A promising youth, son of a former President of Harvard College, put his head under the stream from the nose of a pump one hot day, and died of sudden peritonitis in consequence.

The first lessons of experience must have been often painful and sometimes fatal. Poisonous berries would look tempting; various kinds of dangerous food, or what was taken for food, would play false with those who ventured upon it. When our Pilgrim Fathers first landed on Cape Cod they found certain mollusks on the sandy shore which looked desirable, and were naturally inviting to the half-starved wanderers, long

caged in the little Mayflower. They indulged freely in the unknown mollusks, which, in the expressive words of the old chronicler, did cause them "to cast and to scour," and thus gave them one of those medical lessons which must have been common in the early history of mankind. In this way food, poison, helpful drugs, were first discovered. One notable drug, *nepenthes*, a narcotic, perhaps opium, or hyoscyamus, or hashish, it may be, was known before the days of Homer, for our old friend, handsome Helen of the Iliad, an erring sister, but now reclaimed, as we find her in the Odyssey, and living with her much-enduring husband, mingles it in the draught she gives her guests as a night-cap to ensure their peaceful slumbers.

The next stage of medical history finds the treatment of disease in the hands of priests and sorcerers. How the idea of good and evil supernatural agents springs up in every human tribe I need not attempt to show. But if malignant beings are believed to exist nothing can be more natural than to attribute disease to them. Then the evil spirit must be driven off, — by smoking him out, as in the Apocryphal story of Tobit, or by howling and "making a hellish noise" about the sufferer, as our Indians were wont to do.

Next to the supernatural or magical period would follow in due order that of physical theories. As the phenomena of the macrocosm or outer world were first philosophically studied, the generalizations arrived at would not unnaturally be applied to the microcosm or lesser world of the living human system. So it came about that as four elements, air, earth, fire, water, were recognized in one, four corresponding elements were recognized in the other. These were blood, phlegm, bile, and a fourth less definite fluid known as black bile. Changes in the quality and in the quantity, absolute or relative, of these four fluids were assumed to be the cause of the different diseases to which man is subject. This was the doctrine known as the humoral pathology, that of Hippocrates and Galen, the most prominent one in medical history, and kept in constant preservation to this day by its unconscious emulators, who insist that they are *bilious* whenever their digestion is out of order.

By and by it would be felt that the solid parts of the body, as well as its fluids, must be concerned in disease. Then would come into existence a school of *solidists*, such as the sect known as the *Methodics*, who found the cause of disease to consist chiefly or largely in spasm or relaxation; the *strictum* and *laxum* of Themison, — the physician satirized by Juvenal in the familiar line

Quot Themison agros autumnis occiderit uno.

Behind all these phenomena it would necessarily be felt that there was some *power* at work of which these were the effects; what we should call the vital force; a form of agency which, whether seen in the acts of the individual cell, or the coordinated working of the entire organism, is phenomenally distinguishable from the movements of brute matter. This force, which Hippocrates recognized as *phôris* or *phôresis*, nature or natures, would assume more and more importance as the living actions in health and disease were studied. In this way we arrive at last at the metaphysical stage of the *animists*, which culminated in the *Archæus* of Van Helmont, a conscious agent governing the bodily actions, natural and morbid, and requiring to be man-

aged, to be conciliated, to be governed, without knowing it, as a sharp-witted woman manages, wheedles, and eventually subjugates a refractory husband, and in her turn is bridled, harnessed, and driven by her petted offspring. Whatever other theories we may hold, we must recognize a *ris mediatrice* in some shape or other. "*Je le pensay et Dieu le guarit*" (I dressed his wound and God healed it), was the saying of Ambroise Paré, which you may read to-day on the walls of the lecture-room of the *École de Médecine* in Paris. The operator amputates a limb and leaves a bleeding wreck after him. What surgeon who looks on the rounded and cushioned stump a few weeks later can help owning

"There 's a Divinity that shapes our ends,  
Rough hew them how we will?"

No matter what theory prevails, or has prevailed, physical, metaphysical, humorist or solidist or animist, there always are and always have been those who are content to study disease as they see it, without regard to any *à priori* opinions or deductive generalization. So there is one broad division running through medical history, sometimes, as in the school of Alexandria, separating medical practitioners into hostile camps; that of the Dogmatists and that of the Empirics,—the believers in "*It ought to be, because my theory says so,*" and the believers in "*It is, because I see it.*"

If you wish to know something of these, and of the various theories which have prevailed in ancient times,—I will refer you to the Preface of Celsus to his work *De Medicinis*. Let every student learn enough of Latin to read this, for its clear narrative, its philosophic breadth and dignity, its lesson of simple style and elegant Latinity. Then let him read the treatise of Cabanis on the Revolutions of Medicine,—in French if he can, in the translation if not in the original,—and he will have an outline of the earlier history of his calling which he can fill up at his leisure from the larger histories of medicine. There is a small volume, published within the last year, which contains much that may be found in the two authors I have mentioned, and a good deal more which will prove interesting. Its title is *Medical Heresies*, its author Professor Smythe, of the college at Indianapolis, its publisher Presley Blakiston, of Philadelphia.

I must leave all these, and come to the two modern periods.

The new birth of anatomy dates from the great work of Vesalius, first published in different editions about the middle of the sixteenth century. From the study of normal anatomy arose in natural order of succession the knowledge of the organic changes effected by disease or constituting it. In 1679 Bonetus published his *Spulchretum, sive Anatomia Practica*, a great collection of more or less imperfect accounts of fatal cases, with autopsies and comments, the cases having been gathered from a vast number of authorities. With all its imperfections, this massive work was the foundation for after-builders. From this time speculation about the cause of disease was more and more regulated by the observed changes in the parts affected. The science of Medicine had started on a new career. The publication of Morgagni's work, three quarto volumes, entitled *De Sedibus et Causis Morborum*, established the reign of pathological anatomy, founded by Bonetus. One of the most intelligent of my fellow students, as I remember, read through the three volume of Morgagni, doubtless under the

advice of an instructor. He might have done worse then; to-day he can do better.

Another century passed before the art of healing found a new teacher in the person of a physician who was born with that power of observation, that tact and sagacity, which are the supreme gifts of the practitioner. In the words of the illustrious Dr. Thomas Young, "Physic is one of those departments in which there is frequent necessity for the exercise of an incommunicable faculty of judgment, and a sagacity which may be called transcendental, as extending beyond the simple combination of all that can be taught by precept." This "incommunicable faculty" is the same quality which Cabanis speaks of as that tact which alone can render available at the bedside all the stores of knowledge and all the powers of reason.

The Father of common-sense practice in England was *Thomas Sydenham*, "the restorer of true physic," as Hume calls him, a man whose name is coupled with exalted praise in the pages of Johnson and Macaulay, and gives its title to one of the most useful and distinguished British Medical Societies. He had his hypotheses like others of his time,—he talked about the humors as preceding generations had done, but he kept his eyes open, he watched the progress of disease, he noted the influence of times and seasons, he recognized the meaning of the efforts of nature in the cure of disease. He ordered free ventilation for diseases in which the patient had been "stilled in bed;" he directed horse-back riding for consumptives; he prescribed a roast chicken and a pint of canary for a nervous young man whom the pedants and the pathologists of his day would have probably bled and drenched,—in short, he was a man of excellent judgment and much more than common sagacity, and did not allow his theoretical speculations to blind him to the facts of disease before his eyes. It is almost two hundred years since Sydenham died, but there is wisdom in his writings which never grows old. Many among you know of the late Dr. John Brown, of Edinburgh, by his charming story, "Rab and his Friends." I fear that fewer of you have read his "Locke and Sydenham," and I commend to your special attention this most interesting account of the great English philosopher, who was also a physician, and the great English physician, who belonged to that best class of philosophers who, in the words of an old hymn I half remember,

Not only know,  
But always practice what they know.

You may be surprised that I have not devoted some considerable space to the wonderful discovery of Harvey. But it has been said, and I think with some truth, that no great change in medical practice was effected by this physiological discovery. I will not attempt to investigate the indirect influence it may have had on medicine, and especially on surgery. It is a part of that connected series of ascertained data of the laws of life which, when it does not lead directly to practical consequences, often points the way which experiment is to follow, and on which it remains for experience to pass its judgment.

The last half of the last century was rendered illustrious in medical history by the names of John Baptist Morgagni, Albert von Haller, and John Hunter. Of the first I have already spoken. Haller was the most learned of medical scholars, the stateliest figure in our historical portrait gallery, a man of civic dignities and of literary celebrity, a botanist, a physiologist whose the-

ories have had wide influence, whose work on that branch of science is monumental; a scholar whose three Bibliothecæ, — Anatomica, Chirurgica, Medicinæ Practicæ, — are precious storehouses of medical bibliography, enriched with brief, enlightened criticisms, conveyed in a style at once clear and elegant. Not to know and value his works implies a somewhat narrow horizon of instruction.

John Hunter, unscholarly, obscure in expression, uncouth in diction, bears for all that the greatest name since Harvey's in the annals of English anatomical and physiological science. Two generations ago English and American practitioners held the name of Hunter in such reverence that they almost paused in their speech before mentioning it, as Robert Boyle is said always to have done before uttering the name of the Deity. A great comparative anatomist, a great physiologist, the creator of a vast museum, the author of innumerable original observations of interest to medical science, a surgeon of distinction, a man of powerful native genius, insatiable in thirst for knowledge, indefatigable in accumulating it, his works have been treated as quarries by those who came after him, as the Coliseum was used to build up palaces for the Roman nobles of later ages.

When we come to the broad field of medical practice we shall find that nothing was felt so widely all over it as the jar of that fierce battle between the adherents of Cullen and Brown in the last quarter of the last century. William Cullen had his theories like other teachers, but he was not the less a sound and sensible practitioner. John Brown, the father of the so-called Brunonian system, was essentially a theorist, and deduced his practice from his theory. His doctrines of sthenic and asthenic diseases and the treatment based on his doctrines had a very wide, if a temporary, influence. He had got hold of a truth, but there is nothing more dangerous than a truth allied with a falsehood, a fiction, an illusion, and applied without regard to the language of experience, which the false prophet always interprets to suit himself.

We find ourselves brought down to the close of the eighteenth century and the beginning of that which is now in its last quarter. We have reached a period with the history of which you are supposed to be better acquainted than with that of the long succession of preceding ages over which we have been casting our hasty glances. I need only indicate the leading lines along which the steps of medical progress have passed within the range of our more immediate vision.

The great discovery of the protective power of vaccination against small-pox, made at the close of the last century, came into general recognition in the first years of the present one. *Inoculation*, introduced into England from the East, first into America by Zabdiel Boylston, of Boston, — encouraged, let it be remembered, by Cotton Mather, — had been practised since 1721. In Dr. Waterhouse's collection of papers on vaccination may be found the following table: —

| NATURAL SMALL-POX.<br>A Contagious Disease.  | INOCULATED SMALL-POX.<br>Contagious.  | KINE-POCK.<br>Non-contagious. Never fatal.               |
|--|---|--|
| One to six who take it dies. It is like an attempt to cross a dangerous stream by swimming, where one in six perishes! | One in 300 dies. It is like crossing the stream in an old, leaky boat, where one in 300 perishes. | It is like crossing the stream on a new and safe bridge. |

Next to this, among the grand discoveries which irradiate not merely the foot-path of Medical Science and Art, but the great highway of humanity, is that of

induced anæsthesia. Its cradle was the Massachusetts General Hospital, as surely as Faneuil Hall was the Cradle of Liberty. Not that the earliest hint of either of them was first breathed under those roofs. The Messiah was long promised and expected, but he was born and cradled at Bethlehem. In spite of the not infrequent attempts to appropriate elsewhere the credit of this Heaven-sent gift to mankind, of which the most extraordinary is that of the late Sir James Simpson in the eighth edition of the *Encyclopædia Britannica*, quietly superseded, I am pleased to say, in the ninth edition of the same work, Boston is the Bethlehem of this divine birth, and will, in the light of that fact, remain one of the sacred shrines of humanity as long as the waters wash her feet and the winds blow over her dwellings.

Next in importance to the practical application of anæsthesia we may mention the introduction of physical methods of exploration, — auscultation, formally brought before the world by Laennec in 1819, and percussion, revived by him after more than half a century of comparative neglect. Of this I can speak with some confidence, for I was once well acquainted with it practically, and I have made many an ante-mortem autopsy with my stethoscope and pleximeter. There is no need of insisting on the value of a method of ascertaining the existence of disease so obviously of great assistance. But it may be carried too far, and I am afraid sometimes is so. I have often felt, when seeing hospital patients worried by hammering and long listening to their breathing, in order that the physician might map out nicely the diseased territory, the boundaries of which he could not alter, as if it was too much like the indulgence of an idle, and worse than idle, curiosity. A confessor may ask too many questions, — it may be feared that he has sometimes suggested to innocent young creatures what they never would have thought of otherwise. I even doubt whether it is always worth while to auscult and percuss a suspected patient. Nature is not unkind in concealing the fact of organic disease for a certain time. What is the great secret of the success of every form of quackery? *Hope kept alive*. What is the too frequent fatal gift of science? *A prognosis of despair*. "Do not probe the wound too curiously," said Samuel Sharp, the famous surgeon of the last century. I believe a wise man sometimes carefully worries out the precise organic condition of a patient's chest when a very wise man would let it alone, and treat the constitutional symptoms. The well-being of a patient may be endangered by the pedantic fooleries of a specialist.

Perhaps the medical use of the thermometer is the next in importance of the medical improvements of our century. But of this I have nothing to tell you which you do not know or will not soon learn. Of the ophthalmoscope and laryngoscope I can say nothing of my own knowledge.

With the beginning of the present century we have entered upon a new era, that of General Anatomy or Histology. For an exalted, perhaps extravagant, estimate of Bichat, its illustrious originator, I must refer you to the well-known work of Mr. Buckle. The *Anatomie Générale*, given to the public in the year 1801, changed the whole character of anatomical and pathological investigations. Tissues were studied where organs only or chiefly had been considered, and a new light was thrown on the laws of health and disease.

But General Anatomy was working mostly with

naïved senses, as the astronomers before Galileo explored the heavens. The improvement of the compound microscope, — say rather its new creation, — by rendering its object-glass achromatic, was destined to make a far wider and deeper transformation in anatomy, physiology, and pathology than even the splendid and fertile generalizations of Bichat. Between 1830 and 1840 the results obtained through the use of the perfected instrument began to appear in the great work of Ehrenberg on infusoria, the treatises of Schleiden, Schwann, Henle, Gerber, and many others. From that day to this the microscope has been the Urim and Thummim of the priesthood of biological science.

Its largest revelation has been that of showing the history of the cell and its relation to the organism in health and in disease. We have learned that the law of life in a complex animal organism is local autonomy, with universal suffrage; the individual cell being the citizen of a federal republic; the various departments being distributed among the different viscera, its senate and legislature in the nervous centres, the chief of which is under the dome that crowns the living structure. Here was prefigured what we Americans consider the adult and completed development of civic order.

I cannot resist the temptation of a moment's digression.

Already in the first man who trod the soil of our planet the great mechanical and chemical discoveries of uncounted comings were anticipated. His tissues were woven in a loom no Eastern fingers, no Western machinery, could rival. Where strength was needed a power of resistance like that of iron was given to strands of fibres finer than the spider's thread, seen only as it glistens in the sunbeam. Where elasticity was wanted a substance like caoutchouc exuded and solidified. The pillars which support his frame would crumble under it were they not many times stronger in substance than the columns which support his temples. The leverage of his limbs is adjusted to his needs with an audacity which no engineer would venture. The hydraulics of the circulation are but clumsily imitated in our aqueducts and their distribution. And what are all the flood gates of human contrivance compared to those delicate translucent valves which we were so recently studying, which stand guard at the mouth of the great artery, and arrest the solid column of blood coming back upon them like the blow of a hammer day and night, seventy times a minute, for seventy years; and so many more as life may spare us? Man is more than a machine, but as a machine he is an ever-present miracle. His heart is a time-keeper which counts the seconds for a century with one winding up. The heating apparatus of our dwellings in the surfaces of its radiators and the pots of its furnaces only repeats the valvular connivances and the villi of our own mucous membranes. — No telephone conveys a message so faithfully as the membrane of the tympanum transmits it to the listen in the recesses of the labyrinth. No steam-engine can work with so little fuel as the human organism; no dye house can reproduce the glow of a youthful cheek; no laboratory can manufacture a gram of albumen; no musical instrument can reach the human heart like a woman's voice; no lens can adapt it self to light like the human eye. And so we come back to the microscope, the perfection of which was developed by imitating as it best might those achromatic arrangement, the darkening pigment, the diaphragm, the adjustment for distance, which were all

complete in the first man who opened his eyelids on creation.

The latest great accession to the list of the gains we owe to the microscope is the discovery of the part played by different microscopic organisms in the production of disease and the preventive and curative methods growing out of that discovery.

You must permit me to enumerate in the briefest possible manner some others of the changes that mark the progress of the time over which my own knowledge extends, and which belong to the history of medical science.

The treatment by hypodermic injections has enabled the physician to stay the anguish of dyspnea and arrest the thrills of neuralgia, as the harper stills the quivering cords of his instrument by laying his hand against them. Old measures of treatment have fallen into disuse. Bleeding is almost a lost art, so rarely is it employed. Medicines once in daily request, such as antimonials and mercurials, have taken the back shelves, and left others, the iodides and bromides, especially, in the foreground. Sulphur, "once so prominent," says Mr. Metcalf, "in medicine and theology [is] now almost eliminated from both." "Fifty years ago," he says, "it came at this season into almost every family, like any other form of spring cleaning, and with the same disagreeable results." I need not say how much has been effected in the way of rendering drugs less odious to the smell and taste. Happy the child born since the days of "brimstone and molasses;" who has not sickened in anticipation at the very name of ipecac, and felt his whole life embittered by the flavor of rhubarb!

If I should do more than allude to the subdivision of medical practice into specialties; if I should do more than hint at what the Gynecologists, the Dermatologists, the Laryngologists, and the other long-established specialists have accomplished in their several departments, I should be at the beginning of a volume instead of beyond the middle of a lecture. In surgery the *felix audacia* of ovariectomy has achieved the greatest triumph of operative art. I know by report something of what has been accomplished by antiseptic treatment. American ingenuity has been conspicuous in the departments of plastic surgery and mechanical dentistry. You know what the distinguished Professor of Surgery in this School has done for his art; the world knows it too. How many living surgeons, how many living or dead American surgeons, can claim to have done so much for their branch of the Profession as the man who rekindled the torch of Sir Astley Cooper, and flashed his electric light on the path of Sir Henry Thompson? I may remind you also of the employment of paracentesis, with aspiration, of the thorax in acute disease, the introduction of which has added the names of Bowditch and Wyman to those of the benefactors of the race.

There are many memorable events in recent medical history. Yet there is one gain so vast that we can hardly compare any curative measure with it for importance; I mean the knowledge which has been gained in the art of *preventing* disease; the hygiene of cities, the construction of hospitals, the better study of all those conditions, including climatic influences, which favor health in the two sexes and at different ages.

Leaving the practical side of medical science for a moment, I will barely allude to the results obtained in physiology by the invention of instruments of precis-

ion, like those of Marcy, for instance, and the skilful use of vivisection, a mode of acquiring knowledge justifiable in its proper use, odious beyond measure in its abuse, but not a proper subject of censure to the sportsman who mangles the bird he does not bag, to the fisherman who takes a hundred trout when he does not want more than a dozen, to the huntsman who runs down a fox or a hare until, when he can drag himself no further, he is torn to pieces by the hounds, nay, to the man who asks the blessing of God on what is before him and swallows a dozen living oysters, unless he prefers them as they come from the gridiron, where they have died by the martyrdom of the broiled Saint Lawrence.

It only remains to speak of new methods and theories which have been the product of our century. I will briefly allude to two: the doctrines of Broussais, and the numerical system of Louis. "Broussaïsism" is obsolete, almost forgotten, at the present day. Louis, Andral, Chomel, Trousseau, and others, better observers, and less run away with by theory, killed it. I have heard Broussais lecture often: savage, virulent, a powerful old man, who did more perhaps than we give him credit for to localize diseases which had been considered general; to get rid of what he hated in medicine, *ontology*, and substitute local *irritation* for its ideal diseases, especially to recognize inflammation of a mucous membrane in the place of essential fever.

Of Louis and the numerical system I could say much. He was my loved and honored instructor, and has had a great effect on the medical science of this country through his numerous American students. But I prefer to leave too tempting a subject, only saying this, that the numerical system can teach a wise and honest and diligent man a great deal, and that it can make a foolish, dishonest, careless man a greater fool, impostor, blunderer, than nature ever intended him to be.

In touching upon the subject of Homœopathy I shall find it hard to be very ill-natured. For it so happened that once, on the occasion of delivering a literary lecture, I found myself unexpectedly assigned to the hospitality of a homœopathic practitioner. If my host had consigned me to a chamber in one corner of a compartment of a hollowed-out mustard-seed; if he had offered me the ten millionth dilution of a drop of coffee on a globeule of sugar of milk, and a microscopic fragment of a muscular fibril, with a fraction of a starch cell, and a smell at a pat of oleo-margarine, I might have felt as a patient ought to feel who has been insulted with pharmaceutical infinitesimals equally preposterous and absurd. But I was courteously entreated and handsomely entertained, and in remembrance of that open door and soft bed and well-spread table, I will try to speak of homœopathy, not exactly as Isaac Walton says the angler should treat his frog, "as if he loved him," but at least as kindly as frogs are treated in our physiological laboratory.

The only excuse I can offer for devoting any time to the subject is the fact that it has a certain hold on the community, that it has organizations and institutions which present themselves to the medical student as having a better doctrine and a more effective treatment than what it is pleased to call "the old school," for which "old school" Hahnemann invented the nickname, sometimes used by those who ought to know better, of "allopathy." I require this excuse for introducing the subject, for homœopathy has no *status* among the biological sciences, and has nothing of any

practical value, so far as I know, to offer the Medical Profession. It began by promising to prevent scarlet fever, which it miserably fails to do, and from that day to this it has been a romance of idle promises slipping through the fingers like quicksilver, evaporating without residue like ether from the palm of the hand. If any one of these promises had been fulfilled, if any single remedy brought forward by homœopathy had proved trustworthy and efficacious, it would have been thankfully accepted by the Medical Profession, which welcomes every method of help unless it shows itself with false pretences, and even then will appropriate any fraction of truth which underlies the deception or delusion. *Sanabilia sanantibus curantur*. If a drug is proved to be a remedy for any disease or symptom it is no objection to it that it is capable of producing similar symptoms in a healthy person. It seems to be forgotten that the *Materia Medica* has long recognized a class of remedies under the name of *alterants* or *alteratives*. Under this general head every so-called homœopathic remedy would find its place if any proved really valuable. We might expect that half a century of experience would have something tangible to show for itself.

Forty years ago I delivered and published a Lecture entitled Homœopathy and its Kindred Delusions. The three dogmas with which I had chiefly to deal were these: I quote from the Lecture as published during the year of its delivery:—

(1.) "The one great doctrine which constitutes the basis of Homœopathy as a system is expressed by the Latin aphorism '*Similia similibus curantur*,' or *like cures like*; that is, diseases are cured by agents capable of producing symptoms resembling those found in the disease under treatment."

(2.) "The second great fact which Hahnemann professes to have established is the *efficacy of medicinal substances reduced to a wonderful degree of minuteness or dilution*. The dilution of the original millionth of a grain of medicine contained in the grain of powder operated on is carried successively to the billionth, trillionth, quadrillionth, quintillionth, and very often much higher fractional divisions. A dose of any of these medicines is a minute fraction of a drop, obtained by moistening with them one or more little globules of sugar, of which Hahnemann says it takes about two hundred to weigh a grain."

(3.) "The third great doctrine of Hahnemann is the following: *Seven eighths at least of all chronic diseases* are produced by the existence in the system of that infectious disorder known in the language of science by the appellation of *PSORA*, but to the less refined portion of the community by the name of *TRICH*." "*PSORA* is the sole true and fundamental cause that produces all the other countless forms of disease, which, under the names of nervous debility, hysteria, hypochondriasis, insanity, melancholy, idiocy, madness, epilepsy, and spasms of all kinds, softening of the bones, or rickets, scrofula, and cyphosis, caries, cancer, fungus, hematodes, gout, yellow jaundice and cyanosis, dropsy, — gastralgia, epistaxis, hæmoptysis, asthma and suppuration of the lungs, megrim, deafness, cataract and amaurosis, paralysis, loss of sense, pains of every kind, etc., appear in our pathology as so many peculiar, distinct, and independent diseases." Can you believe that I am not imposing on your credulity when I say that I translate these words literally from Jourdan's French version of Hahnemann's *Organon*?

What has become of the first of these three dogmas? The Encyclopedia Britannica, in its 12th volume, published in 1881, quotes the following confession from a Homeopathic journal called the *Medical Investigator*, of the date of 1876: "How many claiming to be homeopaths are daily disregarding the law of *similia*? It is getting to be quite a rare thing to hear of a homeopathic practitioner conducting a serious case from beginning to end without using as such cathartics, sudorifics, diuretics, etc., in direct opposition to our law; not only are these drugs used in this way, but there are some also go so far as to say that they cannot be dispensed with."

As to the second grand principle announced by Hahnemann, there is abundant evidence that many, if not most, homeopathic practitioners make use of various remedies in their ordinary doses. I have had interesting revelations of this kind from my friend the late Dr. Edward Hammond Clarke. But I was hardly prepared for the statement of Dr. Wilde, Vice-President of the British Homeopathic Medical Society, that "although many believe that the action of the infinitesimal in nature can be demonstrated, its use in medicine is practically by a large number in this country all but abandoned."

The discovery of the *acarus scabiei*, the little insect which proves to be the true cause of itch, has sufficiently disposed of the third of the homeopathic dogmas which I passed under consideration in 1842.

What there is left of a three-legged stool after one of its legs is pulled out, and the other two are sawed half or three quarters through, seems hardly worth sitting down upon.

So far as I can take account of the stock, the present assets of homeopathy consist of a pleasing and sonorous designation, a nomenclature of symptoms, with sets of little pills, containing globules, which are the prettiest and most fascinating of annulets, arranged to correspond with the nomenclature, a collection of "proving" which prove more about the prover than about the questions to be proved, and a doctrine which slips on or off like a kid glove, according to the company in which the practitioner finds himself. Why homeopathy should have so much popular currency in this country as compared with the land of its birth, or with Great Britain, is a curious question. It has been attributed to the state of medical education, but it might be found, I suspect, to be in intimate relations with another very interesting matter, too delicate for me to meddle with here, namely, the potential influence in our community of the imaginative sex, and its psychological leaders and followers.

A few words with reference to Hahnemann, whose vagaries still lie in the way, to be stumbled over by here and there one whose mental twist or imperfect scientific training has betrayed him into the misfortune of taking the wrong direction.

Hahnemann was not an ignoramus, by any means, but something a great deal worse. He was a hopeless subject of cerebral strabismus, beyond all medical, all surgical, treatment. A squinting eye can be set right, but a squinting brain is too much for the art of gods or men. Whether the strabismus involved the moral as well as the mental faculties of Hahnemann, I will not stop to discuss. But when a man misinterprets all that he reads; when he borrows the most foolish things from the most foolish or erratic writers that he can possibly get hold of, then the less he knows about

books the better. In mentioning the authorities from whom Hahnemann probably borrowed his two best known dogmas, I do not mean to say that doctrines originating from unworthy sources *may* not be worthy of confidence. A rogue may have good money in his pocket; but his bills are more likely to be counterfeit than those carried by an honest man.

We know well enough what a braggart and pretender was Bombastus von Hohenheim, who called himself Paracelsus. Even his defenders would recognize him as the very type of the swaggering boasters who profess to work miracles by their wonderful skill and knowledge. Those who are curious will find the distinct statement of the *similia similibus* doctrine in his words quoted in an article in a recent volume of the Encyclopedia Britannica. Whether Hahnemann borrowed it from Paracelsus or not is of no very great consequence, but it is just the kind of hint a shrewd system-maker would be like to find in just the kind of author he would be like to be searching; and its source lays it open to suspicion.

The history of the probable origin of the infinitesimal medication is more interesting, and, so far as my limited reading has extended, has not been unearthed until I happened to strike the burrow the doctrine is likely to have come from.

I chanced to be looking through the *Ortus Medicinæ* of Van Helmont about a year ago, reading here and there as the titles of the chapters attracted me more or less. It was the Elzevir edition of 1652, and had stood on my shelves for many years. Among such titles of chapters as *Blas Humanum* and *Vis Magnetica*, I noticed one with this odd-looking prefix: BUTLER.

I found this was the name of an individual, an Hibernian, a great personage formerly, as he represented, at the court of King James the First of England. At present, however, this distinguished stranger was provided with lodgings at the public expense in the jail of Vilvoorden, a town of Belgium. Here it was that Van Helmont, a very credulous, very whimsical man of genius, a believer in the sympathetic ointment and other nonsense of the kind, became acquainted with the distinguished stranger, who bore the family name of the Duke of Ormond. This captive wrought some wonderful cures, which Van Helmont reports. The first case was that of a monk suffering from erysipelas. The Irishman dipped a certain pebble quickly into a teaspoonful of oil of almonds, and instantly withdrew it. The patient took the oil, or some of it, and was cured at once. Second case: a washerwoman; complaint, hemicrania. He dipped the same pebble quickly into a teaspoonful of olive oil, gave it a lick with his tongue, and put it back in his waistcoat pocket. He poured that teaspoonful of oil into a small vessel of oil. One drop of this to be rubbed on the old woman's head. Immediate and permanent cure. Stupefied astonishment of Van Helmont; — to whom the son of Erin, "My darling, if you don't get on so far that you can cure any disease with a single remedy you will remain a greenhorn (*in tyrocinio*) till you are a greybeard." The next patient was a nobleman; a bad case of gout, as it would seem. He was to touch the pebble every morning with the tip of his tongue, wash the lame parts with a cheap lotion, prepared in the laboratory of nature, and be well in three weeks. If he will make me well, says the count, I will pay him his own price and deposit it, so that he shall be sure of it. Our friend with the pebble

takes this in high dudgeon: will never help the miserable creature; does not want his money; is as good as he is. Van Helmont could not prevail on him to treat the case, and became sceptical. But not long afterwards a fat friend of his wanted to be rid of his obesity. Butler gives him a small fragment of the pebble, which he is to lick once, or touch swiftly with the tip of his tongue, every morning. In three weeks he was a span narrower around his thorax. Van Helmont begins to have faith again, and being himself ill, as he thinks from poison, sends a flask of oil to Butler, who is still in jail, and who dips his pebble in it. One drop to be applied externally in one or more places. Entire failure of relief. Sceptical once more,—our inquiring philosopher. But, next, his wife is relieved of a dropsical swelling, and a servant-maid of an ill-fured erysipelas, and a widow of a stiff arm, all by one or more drops of the oil, and an abatement of loss of power in her right arm by only touching her tongue to the pebble. "Then I asked Butler," says Van Helmont, "why so many women were cured at once, while I, at sword's point with death and full of pains in all my joints and organs, got not the slightest relief." The Irishman gave a plausible answer, which silenced if it did not satisfy the learned simpleton.

The essence of the infinitesimal doctrine is in this most curious chapter of the *Ortus Medicinæ*, which is well worth reading. Hahnemann mentions the name of Van Helmont in his *Organon*, and I have little doubt that he borrowed his infinitesimal doses, smelling of remedies, and other inventions from this chapter. And though such an origin does not prove their falsity or worthlessness, yet we are less disposed to yield our confidence to the pretensions which can be traced to the paternity of so questionable a personage as this exile of Erin.

Van Helmont, I may add, entirely anticipated Hahnemann in insisting upon the use of simple uncompounded remedies. "I believe," he says, "that simple remedies, in their simplicity, are equal to the cure of all diseases." "And consequently," he adds, "the Dispensaries, wishing to compound and correct many ingredients, lose everything, and by a hidden blasphemy, as it were, undertake to supply the divine insufficiency."

Where Hahnemann got his third great dogma, that itch is the cause of seven eighths of chronic diseases, I do not know, but I notice that Van Helmont has a good deal to say about that disease, from which he himself suffered for some months, and what he says may very probably have set Hahnemann thinking about it.

If Homœopathy has made any valuable contribution to therapeutics, of which I do not see the evidence; if it has been of indirect service, like the Unguentum Armarium and the Sympathetic Powder, in showing the public what professional men of common sense have always known, that most diseases can get well without active interference, it has done a vast amount of harm in another direction. I have in my possession one of those foolish little cases of little phials of minute pellets,—homœopathic amulets,—formerly belonging to a friend, now deceased. One at least of its amulet-holders has been largely drawn upon. Its owner watched himself for symptoms, and attacked each as it appeared with what his book told him was its specific. What is the consequence of this daily and hourly self-inspection by all the nervous and crochety owners of these little

seed-capsules of hypochondriasis? They think themselves into every morbid condition they can find a name and a pellet for. These petty engines of great mischief stimulate into consciousness the very symptoms they pretend to subdue, like the rider displaying his horsemanship

While his left heel insidiously aside  
Provokes the caper that he seems to chide.

It is a serious charge to bring, but I appeal to those who know the history of these cartridge boxes charged with imaginary maladies, to say if they have not called into and kept in existence an army of professional invalids.

There are *malades imaginatives* as well as *malades imaginaires*. Such are many of those who have recourse to the globe box as their fetish. The same class of persons, usually, however, in a somewhat different social sphere, have confidence in, and are fond of consulting the *quasi*-supernatural practitioners. A patient of my acquaintance, who died not very long ago while under the care of a homœopathic practitioner, was urged by some who were about her to call in a clairvoyant female. Why not? Would the disciple of Hahnemann have refused to consult with the seeress?

There is little to be done with the *malades imaginaires*; there is nothing to be done with the *malades imaginatives*. All plausible, large-promising false doctrines seize, like epidemics, on their predestined, because predisposed, victims. You will lose a patient now and then to a homœopathist or a clairvoyant; they go where they belong. "Ephraim is joined to idols; let him alone." But do not allow yourself to believe because this new country is the favorite breeding-place of Mormonism, of Homœopathy, of Clairvoyance, that polygamy is going to break up the sanctities of the American household, or the fancy practitioner displace the educated, scientific, rational physician in the abiding confidence of the great American public.

The other pseudo-scientific excrescences growing from the body medical are the systems belonging to the so-called *Eclectics* and to the *Claïrvoyants*. After these come the advertising philanthropists who conduct "medical institutes," and who leave their doors ajar like the covers of so many box-traps.

The Eclectics are the lineal descendants and heirs of the Thomsonians of a past generation, whose botany, as Professor Asa Gray informs me, included not only *lobelia*, but also "*highlobelia*." The eclectic writers and teachers seem to be a sort of half-armed medical militia, of the class that spells inflammation with one *m*, and whiskey without the *e* in the last syllable. I do not suppose their practice differs very much from that of those whom we call regular physicians. One of their "Professors," who recently left the eclectic for the regular ranks of the profession, gives as his reasons that the original and cardinal doctrines of the eclectic school,—opposition to blood-letting and certain mineral remedies on the one hand, and the use of various new remedies on the other,—have been largely adopted by the regular school of medicine. Whatever credit belongs to Samuel Thomson and his successors, the eclectics, let us not deny them. But the real change of medical practice, so far as it can be traced to any individual sources, may with a good show of reason be laid at the door of such teaching as that of Louis on blood-letting, of Dr. Jacob Bigelow on "Self-Limited Diseases," and of Sir John Forbes's "Nature and Art in Disease."

As to the clairvoyants, it seems probable that more patients consult them than we are aware of. Persons who carry horse-chestnuts about with them to keep off rheumatism do not care to have their pockets turned inside out before their neighbors and friends. So the patients of the wise women who see into simpletons, and are seen into by persons of ordinary sagacity, are shy, it may be suspected, of openly entering the sibyl's cave, and follow the example of Nicodemus, the same who came by night to visit his Master.

Do not let the existence of these outgrowths of science disturb your equanimity. The largest and most sensible part of all educated communities will always choose its physicians among those who have the highest mental and personal character, with the most complete training, and who are sure to find each other out and stand united as what we know as the regular medical profession.

The public can form a tolerable opinion of its physicians, — of such men as the late Dr. James Jackson, Dr. Jacob Bigelow, Dr. John Ware, Dr. Edward Hammond Clarke. This is the kind of men in whom the best part of the community always did and always will put its trust.

Of medical theories and practice the community is not a competent judge. Listen to the immortal sentence which stands first among the Aphorisms of the Father of Medicine: —

"Life is short, art is long, opportunity is fleeting, experience is deceptive, judgment is difficult."

If experience is deceptive for the trained practitioner, if a decisive opinion in cases of disease is difficult for him, of what value are the experiences and conclusions of wholly untrained individuals?

Any remedy, any plan of treatment, no matter what it may be, — by rain-water, by Butler's pebble, by homœopathic globules, — which can get itself tried by a thousand persons will be sure of formidable evidence, or what seems like it, in its favor. Of the thousand patients, nine hundred, we may say, will certainly get well, however they are treated. One hundred will begin taking the remedy somewhere near the time when they were to become convalescent. Fifty, or twenty, if you will, will happen to find themselves almost immediately relieved after taking the remedy or beginning the plan of treatment, and this on the supposition that the remedy is absolutely without virtue, and has nothing to do with the cure. How can you argue with these fifty or twenty people? They answer exactly in the same way with the blind man restored to sight, told of in the Gospel of Saint John. Whether this be a quick remedy, or no, I know not; one thing I know, that whereas I was sick, now I am well. And this argument, utterly fallacious as proof, will prove a sure defence to every form of quackery until the end of time. The underlying fact is that the great proportion of diseases tend to get well spontaneously, and a considerable crop of striking coincidences, looking like cause and effect, will spring up in any large field where any alleged remedy has been sowed broadcast.

Homœopathy, like every other system, true and false alike, has the advantage of this kind of deceptive evidence. The best thing it has effected has been to diminish the quantity of odiously-smelling and tasting drugs with which patients, especially children, who could not help themselves, were by too many old-fashioned practitioners often unnecessarily dosed. This

one good influence we may in some measure, at least, attribute to the inoffensive, inert, utterly useless "globules," having all the virtues a name can give them, and no others. Not the less is homœopathy a system of false pretences. Who had not rather see "little Jack Horner" and similar myths in the nursery than books like the Newgate Calendar, full of true stories which would frighten the poor children out of their senses? But if a man comes along professing to teach history on the basis of Mother Goose; if he alleges as a scientific fact that a man did really scratch out his eyes by jumping into one bush, and did really scratch them in again by jumping into another similar bush, and takes this fact for the corner stone of ophthalmic surgery, I do not think the Professors of Harvard University would feel themselves called upon to recognize him as a scientific and professional fellow-worker.

Again, we must not deny that there is such a thing as the *faith-cure*, quite independent of any special divine intervention. Every form of medical imposture can shew such cures, for the imagination is a very powerful physiological agent. They are numerous just according to the impressibility and the credulity of the class to which the impostor appeals. Women are oftener cured than men; nervous diseases oftener than others; peasants oftener than princes; poets oftener than men of science; clergymen more frequently than lawyers; Catholics are more favored than Protestants, — see the "collection of crutches" at Mount Ste. Anne figured in *The Century* for May. Such are the incidental good effects which the worst cheat who ever sold rain-water as a precious remedy for all evils may challenge as the result of his mendacity and impudence.

Let me illuminate the closing passages of my lecture with some words from three great authorities, whose names will add weight to its utterances: —

"Whatever efforts," says Cuvier, "have been made in the course of long ages by the men of genius who have practiced medicine, none of the doctrines which they have proposed under this name [medical theory] has obtained lasting assent. Young persons adopt them, each time as they come up, with enthusiasm, because they seem to abridge study, and furnish the clue to an almost inextricable labyrinth; but the briefest experience disabuses them."

And Helmholtz says, speaking of old theories, "If I were called upon to designate in one word the fundamental error of that former time, I should be inclined to say that it pursued a false ideal of science in a one-sided and erroneous reverence for the deductive method."

No, gentlemen, there is no exclusive *a priori* method which leads to the successful treatment of disease. You begin in the priuorse paths of knowledge which are only preliminary to your real work. Anatomy is no more medicine than a child's dissected alphabet is literature. Physiology and chemistry throw gleams of light here and there on curative methods, but are apt to lead their votaries far away from practice. Pathological anatomy teaches a great deal, but it is, after all, like inspecting what is left of the fireworks on the morning of the fifth of July. It is very pleasant to dissect a muscle, to make a precipitate, to watch a contracting heart, to study a translucent slice of a healthy or diseased organ. These pursuits, sisters of her who pre-

<sup>1</sup> Hist. des Prog. des Sc. Nat., 1, 150.

sides over health and disease, are the sirens that won over Agassiz and Huxley and Helmholtz to their flowery realisms. But just as zoölogy, chemistry, physiology, histology, are not the science of medicine, so neither is the science of medicine the same thing as the art of healing. To go hastily from the library of old books and the laboratory of new experiments to the bedside of disease is imitating the presumption of those rash profligates who, as Thomas Boston says, think they can take a "leap out of Delilah's lap into Abraham's bosom."

The medical student is in little danger now from the old theories which blinded the eyes of observers in former ages. He is more likely to forget his practical work,—which means giving his whole thought to the lesser as well as the greater needs of his patient, to all the little details of the sick-room,—in the fascinating pursuit of his scientific investigations. I would not undervalue the branch I teach. I recognize the incidental importance of all the subsidiary branches which form a part of the curriculum of this and other schools. Do full justice to them, or you will not probably do justice to your more immediately practical studies. But your hardest study must be at the bedside. Your real business will be to save life, to avert disease, to manage it so far as manageable, to save your patients all unnecessary suffering. And so doing may each of you be able to repeat the noble words of Thomas Sydenham, with which I will close this lecture. Two hundred years have passed since they were written, and they still speak in accents that can never grow old:—

"And, in truth, when I come to die, I trust I shall have the satisfaction of being inwardly assured that I have not only endeavored, with the utmost diligence and integrity, to recover the health of all those who have been my patients, of whatever rank or condition they were, none of whom have been otherwise treated by me than I desire to be, if I should be seized by the same distempers; but also that I have contributed, to the utmost of my abilities, that the cure of diseases might, if possible, be prosecuted with greater certainty after my decease; being of opinion that any accession to this kind of knowledge, though it should teach nothing more pompous than the cure of the toothache, or corns, is of much greater value than all the vain parade of refinements in theory, and a knowledge of trifles, which are perhaps of as little service to a physician in removing diseases, as skill in music is to an architect in building."

### CASES OF WRY NECK.

BY E. H. BRADFORD, M. D.,

*Surgeon to the Children's Hospital, Boston.*

CASE I. L. T., nine years old. The patient presented herself for treatment, with the following history: Nine months before she was suddenly seized, without known cause, with pain in the head and neck. On the following morning her head was permanently drawn to one side. After a while the pain disappeared, but the distortion of the head remained the same.

The child's general condition was good, and she complained of no suffering or trouble in respiration; the position of the head was so fixed and the distortion was such that in walking in the street she occasionally ran into people, being unable to see them on account

of the abnormal position of the face. From the line of the spinous processes in the cervical region it was evident that the spine was twisted to a marked degree. The head was movable to the right but not to the left. The muscles of the neck were not contracted, except the posterior muscles.

From photograph just before operation.

The patient was etherized, her shoulders were steadied by assistants, the head grasped between two hands placed on each side, and the deformity slowly rectified by manual force. The tendon of the sternomastoid was brought into prominence and divided by tenotomy, without evident advantage, however. Fibrous adhesions were felt to give way in the region of the spine, and after a time the axis of the face was brought in line with the axis of the trunk. It was found that a great deal of force would be required to correct the deformity, and it was not thought prudent to attempt this. In moving the head back toward the line of deformity it was felt to slip suddenly, as if returning to a position natural to the altered articular facets: on correction, however, the normal position was retained.

From photograph two weeks after operation.

A plaster-of-Paris jacket was placed around the trunk, covering the shoulders, and a steel rod secured in it reaching above, and bent so as to partly encircle the head. Silicate-of-potash bandages fastened the

head to the steel support and kept the axis of the face in the normal position. No disturbance followed the operation, and three weeks later the patient was again etherized, in order to gain, if possible, still farther motion in the neck to the left. But little, however, was accomplished in this direction.

The patient subsequently wore for three months a steel collar adapted so as to hold the head in a proper position, and since then has been without apparatus. At the present time, ten months after operative interference, the patient has shown no evidence of a relapse, the position of her head being that indicated in the picture. She has enjoyed the ordinary activity of children. Motion at the atlas-axoid articulation is perfect. Motion in the cervical spine below that is somewhat limited.

**CASE II. II.<sup>1</sup>** The patient was a boy, nine years old, suffering from wry neck of three months' duration, which was said to have begun with pain and swelling behind the right ear. The face was turned to the right, and the left shoulder was raised higher than the right. Any attempt to turn the chin to the left of its position was unsuccessful and caused pain, but the chin could be moved farther to the right. The posterior muscles of the neck on the right side were hard on palpation. The sterno-cleido-mastoid muscles were flaccid.

After various unsuccessful attempts to correct the deformity by means of poultices, leeches, embrocations, and appliances, the boy was etherized, and the head placed in a normal position and fixed by the use of silicate-of-potash bandages, strengthened by a steel strip (holding the trunk and the head). The bandage was worn for a month. After its removal the head remained straight.

Two years later the boy was heard from, and reported to have remained without relapse.

**CASE III. M. G.,** a girl nine years old, was affected with torticollis, the chin being turned to the left; the right sterno-cleido-mastoid muscle was contracted, but there was no evidence of the implication of any other muscle. The deformity had come on gradually, and had persisted for the past two years.

The patient was etherized, and the insertions of the sterno-mastoid muscle were divided. The head and trunk were immediately encased in a plaster-of-Paris bandage, firmly fixing the corrected position. In a week a modification of Mr. Swan's method (to be described later) was applied and worn for two months. There has up to the present time, five months after the operation, been no tendency to relapse.

**CASE IV. S. C.,** a boy six years old. This case resembled the preceding, except that the deformity is stated to have persisted since birth. A marked depression is to be found over the left eye in the frontal bone, which was said to be due to the blade of the forceps used at birth. The mother is led to attribute the deformity to this. The patient is perfectly healthy.

Tenotomy of the sterno-mastoid was performed, and the head placed immediately in a corrected position, a plaster-of-Paris jacket being applied to the trunk, and adhesive plaster and straps applied to the head and, by means of buckles, fixing the correction. This appliance was worn six weeks. At the present time there has been no tendency to relapse.

**CASE V. K.,** delicate girl six years old, came under treatment for a slight distortion of the head, which had,

without known cause, persisted for six months; the chin was turned to the left, so that the axis of the face deviated from that of the trunk twenty degrees. The head could be turned in every other direction, but it was impossible to bring it to the normal position. The sterno-mastoid muscles were not affected, those at the back of the neck causing the deformity. One shoulder was held higher than the other, and a marked curve in the upper dorsal region of the spine was to be seen.

After four weeks' persistent treatment with various appliances, including, among others, the excellent arrangement of Dr. Shaffer, of New York, the head was brought to a normal position; the motion became perfect, and the curve in the back was corrected. No anæsthetic was used, the head being corrected by the use of apparatus alone.

The greatest amount of improvement was gained by the use of an appliance which supported the chin, and thereby took the strain caused by the weight of the head from the posterior muscles of the neck. This was readily accomplished by the wire collar of Dr. Buckminster Brown. The child wore this appliance for two months, to prevent relapse, and continued to be perfectly free from deformity after its discontinuance. At the present time, one year later, she is reported to be in perfectly normal position.

**CASE VI. M.,** a gentleman, forty-five years of age, of exceedingly nervous temperament, who for many years was an active stock-broker in New York, was, on account of increasing nervousness, obliged to give up his business, which had been a prosperous one. He had been affected for some time with clonic spasm of the muscles of the neck, which twisted the chin to the right side. This was most noticeable when he walked, and at times his head remained perfectly straight. Steadying his head by applying a cane to the side of the face prevented the twisting of the head. A compensatory curve of the spine was noticed. Thorough treatment by the application of plaster-of-Paris appliances and section of the spinal accessory was declined.

**CASE VII. K.,** a woman twenty-eight years of age, of slight build and nervous temperament, became, without known cause, afflicted by a contraction of the muscles of the neck, which turned her head to the side, so that her chin was nearly above the right clavicle. This was most marked when the patient walked; some days it would be worse than others, and the deformity was worse as the patient was noticed or became nervous. Electricity and medical treatment were tried without benefit. Appliances were worn constantly for one month, and for three months regularly, which held the head in position, but no permanent benefit followed. Section of the spinal accessory or a plaster-of-Paris bandage was declined. The muscles most noticeably contracted were the posterior muscles in the neck; the sterno-mastoid muscles were not affected.<sup>2</sup>

**CASE VIII.** Healthy boy, nine years, whose sister had, one year before, been cured by tenotomy of a torticollis of several years' duration, was noticed by his parents to twist his head slightly. This gradually increased, and at the end of six months a marked persistent torticollis, with contraction of the right sterno-mastoid, was to be observed. No evidence of neuro-mimicry was to be noticed on watching the patient, and tenotomy is to be done.

<sup>1</sup> The New York Medical Journal, January, 1880.

<sup>2</sup> For a similar case vide Boston Medical and Surgical Journal, April 27, 1882, page 336.

**CASE IX.** Healthy child, six weeks old, was brought for treatment with well-marked torticollis, the chin being turned to the right. This had appeared since birth, which had been a difficult one. On palpation the left sterno-mastoid was found to be ruptured three quarters of its entire width, the untorn fibres were spasmodically contracted. The child did not return for treatment.

**CASE X.** A girl, ten years old, while in bed, after an attack of what was termed febricula, was pulled by the head, in play, by her sister, and on the following night suffered great pain in the head and side of the neck; the head was pulled to the side so that the ear rested nearly upon the shoulder. After a week a slight rectification of the deformity took place, and an enlarged gland could be felt in the region between the sterno-mastoid and the trapezius. The pain, which had been severe, suddenly disappeared, the tumor formed by the enlarged gland became larger, and fluctuation was felt, and incision advised, but not done. The swelling, however, was gradually absorbed, and the head slowly rectified itself, and at the end of three weeks the position and motion was perfectly normal, and has remained so for the past eight months. The sterno-mastoid muscle was not involved in this deformity. At the present time, six months after recovery, the patient has remained perfectly well.

**CASE XI.** A case seen in consultation with Dr. Doe, the patient being a woman of about twenty years of age, recovering from typhoid fever. The distortion was quite marked, and the head was well fixed in the distorted position by a spasm of the posterior muscles of the neck. Recovery slowly took place, the rectification occurring spontaneously.

**CASE XII.** P., healthy child, six months old, was

Centre of forehead.

born with a lack of symmetry of the cranium, affecting the frontal bone on the right side in such a way that from the orbital region upward the face appeared to be flattened, the frontal eminence, the supraorbital ridge, the malar bone being all less prominent on the right than the left side. The face and head in every other respect was symmetrical. The child appeared to be healthy, and was as intelligent as children of its age. The trunk and limbs were normal.

Position usually assumed by the child. The shaded portion indicates the region of flattening.

The head was carried habitually in the position of wry

neck, with the chin turned to the right, exactly in the position to suggest the explanation by the mother that the left side "was heavier than the right, and the head was held crooked." No paralysis existed, and the child could move the head in all directions voluntarily, no contraction being present. The usual position, however, was the one described; a slight secondary curvature of the spine was present, and in consequence the shoulders were held one higher than the other.

The cases illustrate the variety of causes<sup>1</sup> which produce the deformity called wry neck, and also the fact, overlooked in many of the text books, that the sterno-cleido mastoid muscle does not always play the most important part in the production of the deformity, a fact clearly shown by Delore,<sup>2</sup> who claims that "posterior torticollis" is the more common form.

In wry neck from caries of the spine in the cervical region, the posterior muscles of the neck are those chiefly involved. Any irritation, however, at the base of the head will produce a similar deformity, as in Case II. and Case X. The distortion appears to be sometimes due to a neurosis, as in Cases III., VI., VII., and VIII. Of these three were affected in the sterno-mastoid alone, and two in the posterior muscles of the neck. In Case IV. a connection between the indentation of the skull and the wry neck is of course possible, but, in view of the facts presented by Case IX., hardly probable.

It would be difficult to class Case V. under any head unless that of a neurosis, and possibly Case XII. could be considered in the same way.

A variety of wry neck has been described by French writers as due to an inflammatory affection of the articulations in the cervical spine. It is possible that Case I. could be classed in this category. The patient had suffered from some process which affected the spinal column in the cervical region, as was evident from the fibrous adhesions, which gave way on rectifying the deformity. It might be otherwise considered a rare form of cervical caries where the process had undergone a spontaneous arrest after a short course. For nearly a year after the original seizure until the time of the operation no symptoms were present indicating caries, and up to the present time, ten months after operative interference, no evidence of caries is to be found.

The treatment employed in the cases which were treated was, in Cases I. and II., that advised by Delore, namely, rectification under an anæsthetic, and immediate fixation. Silicate of potash bandages recommended by him for fixation were used in Case II., but subsequent experience showed the advantage of plaster-of-Paris. In Cases III. and IV. a modification of the arrangement described by Mr. Swan<sup>3</sup> was used. This consists of a plaster-of-Paris jacket to hold the trunk and shoulder, into which buckles are fastened. A hold on the head is secured by applying the ordinary head bandage, encircling the head from occiput to forehead, and from vertex to chin. As this would slip, a piece of rubber adhesive plaster is first applied on the forehead, and the beginning of the bandage is sewed to the end of the adhesive plaster. After the bandage is applied in the ordinary way it is to be stitched at the points of crossing, and webbing is sewn on at such

<sup>1</sup> Cases of wry neck occurring in the ordinary course of cervical caries are not referred to in this paper.

<sup>2</sup> Gaz. Hebdomadaire, March 15, 1878.

<sup>3</sup> Dublin Journal Medical Sciences, August, 1879, page 114.

places as will, when fastened to the buckles on the jacket encasing the trunk, twist the head in the direction desired. The exact places for the buckles and straps can be determined only by experimentation in each case. Perineal straps to hold the jacket from rising are of use.

As a portable appliance to be used as after-treatment to prevent relapse, the wire collar devised by Dr. Buckminster Brown leaves little to be desired.

# REMARKABLE CASE OF SACCULATED OR OF CIRROID ANEURISM OF THE SECOND INTEROSSEOUS BRANCH OF THE DEEP PALMAR ARCH TREATED BY EXCISION.<sup>1</sup>

WITH EXHIBITION OF THE SPECIMEN.

BY JOHN B. ROBERTS, M. D.

*Lecturer on Anatomy and on Operative Surgery in the Philadelphia School of Anatomy.*

The specimen which I exhibit this evening and its accompanying history are interesting, I think, because of the extreme rarity of the condition. I know of no similar case reported; but I have not had an opportunity to search for such in medical literature, because the operation was performed only a few hours ago. The specimen is fresh, and is exhibited now before the appearances have been changed by any preservative fluid.

Dr. Charles H. Thomas requested me a few days ago to assist him, at an early date, in operating upon a tumor of the hand in a boy, aged sixteen years. From his earliest childhood he had been under Dr. Thomas's observation, and had had a small elongated tumor upon the dorsal surface of the first phalanx of the left ring-finger, while in the palm, at the junction of the bases of the middle and ring-fingers, was a larger swelling. These were considered masses of dilated veins, as they had a spongy feel, and at times showed a bluish color. There was no very definite connecting band of swelling between the dorsal and palmar enlargements. No special pain was experienced unless the parts were struck, and no marked growth occurred. Hence the child's mother was advised to have nothing done. As the boy grew, the hand and tumor increased, but held the same relative proportions. When the boy began work in a machine-shop, the skin became thickened and soiled, and the bluish tint was no longer discernible.

About two months or less ago, the growths seemed to enlarge and to be accompanied by considerable pain, and Dr. Thomas advised the use of a compress in the palm and a bandage around the finger. This the boy wore at nights, and usually from Saturday to Monday morning when he returned to his work. Recently there was noticed pulsation in the palmar tumor and a lobulated feel; and Dr. Thomas feared that an arterial aneurism existed.

When I examined the boy last evening, I found on the back of the third finger a hard fibrous-like tumor, as large as a watermelon seed, with the long diameter corresponding to the length of the phalanx. In the palm was an illy defined swelling covered with thick skin, very sensitive to pressure, and occupying about the area of a silver half-dollar. No swelling was evident connecting the two tumors. On the ulnar side of

the palmar mass moderately distinct pulsation could be felt, which quickly stopped when the radial artery was compressed at the wrist, but merely decreased in force when the ulnar was pressed upon with the finger. No pulsation was felt in the dorsal tumor.

The boy had severe pain even when no pressure was made upon the growth in the palm.

I gave it as my opinion that the growth was an arterial angioma connected with the second interosseous branch of the deep palmar arch, having anastomoses with the digital branches of the ulnar artery. Dr. Thomas considered it possibly this, but probably a sacculated aneurism. His diagnosis has proved to be the more correct.

It was determined to employ the Esmarch elastic bandage, and to make a free incision over the tumor and dissect it out, whether it be angioma or aneurism. As Dr. Thomas was disabled by a painful boil on his right hand, he requested me to operate. The boy was etherized and the elastic bandage applied.

I made an incision from a point a little in front of the superficial palmar arch to the commissure of the fingers, and came upon a mass of fat and small vessels, in the centre of which was a bluish nodule, resembling larger vessels containing blood not driven out by the elastic bandage. Keeping close to the skin, and going down to the sheaths of the flexor tendons, I dissected the mass free. Lying alongside of the palmar interosseous muscle going to the ring-finger (second interosseous) we saw a comparatively large vessel which seemed to be the main feeder of the mass. I then extended my incision, making a straight cut along the side of the ring-finger, dissected up the skin, and enucleated the hard nodule lying on the back of the first phalanx. This seemed connected with the other mass by some fibres or small vessels, and both were removed as one piece. The wound was then plugged with dry muslin to stop the general oozing that occurred after removal of the bandage, and a tight bandage applied. No ligatures were required, because my incisions were made at a distance from the tumor.

Dissection of the palmar mass showed that I had removed a small body, about three quarters of an inch in diameter, containing clotted blood, and surrounded by adipose tissue and nerves. Small collapsed vessels in large numbers may perhaps be found in this adipose tissue by microscopic examination. Only a few larger ones were recognizable by ocular inspection because of the absence of blood from the interior. The tumor, as is seen on the plate, consists of three lobules of rather unequal size, arranged somewhat as a trefoil. The largest one of them, which has been punctured, allows the escape of soft clot; this sac is about one half an inch in diameter. The three sacs seem to be separate, because the head of a pin introduced into one does not pass into the others. The two smaller sacs or lobules are hard, as if the clot was old. One has been laid open, and shows a white centre, or nucleus, of cartilaginous consistence surrounded by a layer of red clot. On the surface of this three-lobed tumor runs a nerve, which probably was the seat of pain from pressure, and parallel to it a small artery. Both of these become lost in the mass, at the upper end of the tumor, which was thought to contain the main supply of the aneurism, and around which a string was tied and left for identification.

The tumor from the back of the finger is hard, and on section shows an irregularly colored red surface.

<sup>1</sup> Read May 3, 1882, before the College of Surgeons of Philadelphia.

I believe the tumors, therefore, to be small sacculated aneurisms evidently allied to or identical with the variety called cirroid aneurism. The one on the back of the finger and the two smaller lobules in the palm are undergoing cure by coagulation, induced in the dorsal one undoubtedly by the pressure from the bandage used at intervals during the last six weeks or two months.

If the diagnosis had been more certain as to aneurism, I believe that digital compression of radial and ulnar arteries, or the use of an Esmarch elastic bandage to the forearm, would have been proper treatment before excision was attempted.

The early period of life (about three years) at which the trouble was noticed primarily renders it probable that the aneurisms were not originally traumatic. It is possible, I suppose, that the vessels of an arterial angioma may have become so dilated as to resemble these multiple aneurisms.

The similarity to cirroid aneurism is certainly very great, though there are some points which differ somewhat from the usual clinical history of these growths.

[After the reading of the preceding paper:]

Dr. W. W. Keen called attention to the danger of using coagulating agents in such cases, and spoke of a case of traumatic origin he had seen in consultation, in which a few drops of Monsell's solution had been injected into the aneurismal sac, and gangrene had followed, necessitating amputation of the hand. He thought compression of the radial and ulnar arteries would probably have accomplished a cure, and the risks of an operation would have been avoided. With regard to the small tumor on the dorsal surface of the ring-finger, he thought it unlikely to be an aneurism. Nothing short of a microscopical examination would determine its nature.

## RECENT PROGRESS IN OPHTHALMOLOGY.

BY O. F. WADSWORTH, M. D.

### THE NATURE OF TRACHOMA AND SOME OTHER DISEASES OF THE CONJUNCTIVA.

SATTLER<sup>1</sup> considers the trachoma granules to be a specific product, and the most characteristic anatomical sign of the trachomatous process. He denies that they arise from an enlargement of lymph follicles normally present in the conjunctiva, or that any such exist in the normal conjunctiva. Instead of the granules being lymph follicles, they consist, aside from a network of capillaries, of round or oval nuclei, imbedded in a finely granular substance, and of fragments of nuclei. These nuclei are not surrounded by protoplasm as are the nuclei of the lymphoid cells of the conjunctiva.

In the secretion from the various stages of trachoma, Sattler found a single form of microbion, a circular micrococcus, somewhat less in diameter than the micrococcus found in blennorrhœa, but which in its forms of growth, as shown by cultivation, agrees with the latter in all essentials. Always in active movement, the micrococci were seldom single, occasionally in pairs, but more often three or four together, arranged in the form of a triangle or quadrangle of nearly equal sides. This arrangement seemed characteristic both in the trachomatous and blennorrhœic secretion. They were often

attached to the surface of epithelial and pus cells, also within the latter in contact with the nucleus.

If trachoma be, as generally assumed, a local disease, caused by infection, and the micrococci be the bearers of the infection, and determine by their action the character of the disease, they should be found not simply in the secretion of the mucous membrane, but in the tissues of the conjunctiva itself. A trachoma granule was excised under antiseptic precautions, its contents carefully removed and placed in the conjunctival sac of another individual, and in seven days evident signs of the disease appeared. It is of interest to note that in this case, in the earlier stages of the disease, and up to a certain point, no clinical distinction between it and the so-called follicular swelling or follicular conjunctivitis could be seen. Further, the contents of a granule were placed in sterilized solutions and in isinglass jelly, and the development of the microbion watched. Inoculation from a well advanced cultivation of this sort also produced the disease after a time of incubation of eight days.

Anatomically the micrococci were found in the granules, both in sections and in the spread-out contents, attached to nuclei and fragments of nuclei. The nuclei showed changes, particularly in their size and behavior toward coloring matters. These changes were not only regressive but also progressive; there were plain indications of division. But besides pathological alterations in the granules, these occur also in the surrounding tissue; nuclei, isolated or in small collections, were seen, which were larger, and colored less readily than normal, and were beset by micrococci.

In the older granules of trachoma there is often a thickening of the adventitia of the vessels, which may go on to an obliteration of their calibre and their transformation into a solid cord, and this, Sattler believes, bears an important part in the so-called connective tissue change. Another source of connective tissue is found in the stationary elements of the "capsule," and in advanced cases, especially in the hypertrophied papillary forms, there are often signs of new formation of connective tissue in the lymphoid infiltrated conjunctiva. He could, however, find no evidence that the elements of the granules themselves underwent this transformation, and thinks that, in general, formation of connective tissue as a result of the trachomatous process has been overestimated, and that in many cases, at least, there is rather, with the gradual disappearance of the granules, an atrophy of the conjunctiva.

The formations described as glands by Iwanoff and Berlin in advanced cases of trachoma, Sattler asserts he has been familiar with for years, but agrees with other writers that they are not new-formed glands, but the appearances seen are produced by infoldings of the surface during the irregular swelling of the tissues.

The follicles in the so-called follicular conjunctivitis also contain micrococci, and are distinguished anatomically from trachoma granules only by their exclusively superficial situation, by a relatively greater number of intact or slightly altered nuclei, and by some unimportant differences in the capillaries and frame-work. Both in this affection and in trachoma there is often an extensive infarction of the lymph vessels with lymphoid cells.

In an instance under Sattler's observation, a mother, suffering from moderate leucorrhœa during pregnancy, gave a light blennorrhœa to her infant, and she herself being infected from the child, developed trachoma.

<sup>1</sup> Bericht der Ophthalmologischen Gesellschaft, Heidelberg, 1881.

From this case, and from consideration of the generally admitted fact that blennorrhœa of infants is caused, under certain conditions, by simple leucorrhœa, he holds that a close relation between the excretors of infection of these different affections is not to be lightly denied, and that it is not improbable that the micrococcus causing trachoma is derived from that which flourishes in the vaginal secretions.

As to the much discussed question of transportation of infection through the air, the micrococci certainly may be carried in the dust arising from powdering of the dried conjunctival secretion. It is probable, however, that the micrococcus is often killed by drying, yet it is possible that under certain conditions its vital energies are weakened, not destroyed, and, as in crowded school-rooms, it may then excite in a number of individuals a disease, which, clinically and anatomically like the early stages of trachoma, does not lead to deeper changes, and, though it may be obstinate, heals of itself when the person affected is removed from harmful influences.

In the discussion which followed the reading of Sattler's paper, Goldzieher mentioned a circumstance corroborative of the idea that all infectious diseases of the conjunctiva may have the same origin. A boy who had lost his eyes from a blennorrhœa was admitted to a blind asylum in Budapest, and an extensive epidemic followed. But among those affected there was observed a great variation in the character of the disease, some contracted a pure blennorrhœa, others true trachoma, while there were also instances of intermediate forms.

#### PROPHYLAXIS OF OPHTHALMIA NEONATORUM.

Crédé<sup>1</sup> has now treated four hundred cases in addition to two hundred previously reported,<sup>2</sup> and with equal success. In consequence of the objection that the continued application of salicylic acid compresses was very probably the important part of the treatment of the earlier cases, the compresses were omitted in more than three hundred of the later ones, and the treatment thus rendered exceedingly simple. On division of the cord the infants were bathed, the lids washed off with a bit of clean rag and water only, then from a glass tube a single drop of a two per cent. solution of silver nitrate was dropped into each slightly opened eye. Nothing more was done. No one of the infants so treated became affected during the first seven days, even in slight degree, nor was there the least harm from the instillation. Children born at term showed practically no reaction, scarce reddening, never swelling. Only in a portion of the prematurely born, whose conjunctiva appears to be more easily irritated, there was after a short time an increased serous, followed by a little mucous secretion, which, however, always disappeared in twenty-four to forty-eight hours. Crédé insists that only direct treatment of the eyes themselves is a certain preventive of infection. Disinfectant cleansing of the maternal genitals before and during labor, though this also was carried out as much as possible, has been shown by experience to be insufficient of itself to prevent infection, and none of the other usual disinfectants has given the same certainty as the silver nitrate.

The mothers of the six hundred infants presented the most varying conditions; there were syphilitic,

gonorrhœal, and catarrhal affections; some were clean, others very dirty, and the latter could not always be properly cleansed because entering the hospital during labor; there were easy labors, and very severe operative cases.

The above treatment, of course, prevents only such disease as is acquired during labor; this, it is generally admitted, appears at latest on the fifth day. Any affection beginning later must be referred to another source. The later cases occur but rarely, and their course is generally short and favorable, although serious cases are sometimes observed. For these a drop of the above solution should be applied at the beginning, repeated once daily, if necessary, and a small ice-bag be kept continuously on the lids.

#### THE MECHANISM OF SYMPATHETIC OPHTHALMIA.

In what way the inflammation of sympathetic ophthalmia is conveyed from one eye to the other has never been satisfactorily settled. The spread of inflammation directly along the optic nerve and through the chiasma or its development from a reflex irritation carried by the ciliary nerves, these are the theories which have been generally held. The latter has had by far the most numerous adherents, while some have believed that both were correct, and that sometimes the optic, sometimes the ciliary nerves were the agents of transmission, or that they might act together in the same case. Recently the lymph spaces have been brought into prominence as furnishing the path by which the morbid process travels to the second eye.

Mac Gillavry, in 1879, at the International Congress at Amsterdam,<sup>3</sup> gave the results of anatomical examination of an eye which had set up sympathetic ophthalmia. He found collections of lymphoid cells blocking the sub-dural lymph space of the optic nerve, and suggested that similar obstruction within the cranium might lead to the transportation of inflammatory products into the lymph space of the opposite optics. Such an explanation of the mechanism of sympathetic ophthalmia he thought more rational than to attribute it to an inflammation proceeding along a perhaps atrophied optic nerve, or to a mere reflex.

In the same year Knies,<sup>4</sup> at Heidelberg, described a case of double iritis serosa in which the arachnoid sheaths of both optics were thickly infiltrated with cells close up to the chiasma. The chiasma itself was not examined, but there could be little doubt that the infiltration was continuous from one nerve to the other. Although this was not a case of sympathetic inflammation, Knies thought it of importance as showing a probable method of transmission of that disease.

Leber<sup>5</sup> not only regards the lymph spaces of the optics as the path, but microbes as the cause, of the affection. The character of the inflammation, the fact that in a great majority of cases there has been a wound of the eye, in others an ulcerative process which has given opportunity for the entrance of germs, that as a rule a definite time, six or eight weeks, is required for the spread of the disease to the second eye, support this view. In the rare instances when the second eye is only inflamed years after the original injury there is an exacerbation of the earlier inflammation or a fresh infection of the first eye. Sympa-

<sup>2</sup> See JOURNAL, vol. cv., p. 412.

thetic irritation is indeed conveyed by the ciliary nerves, yet this does not of itself excite pathological changes, even if the irritation continue for years. Complete anatomical proof of the theory is difficult to obtain, but he has repeatedly found low organisms in eyes enucleated to avoid danger of sympathetic inflammation, and in an eye removed after inflammation had broken out in the second there were microbes to be seen in the tissue between the nerve sheaths and in the atrophied nerve substance.

Snellen<sup>1</sup> also has found micrococci in the choroid and sheaths of the opticus of eyes enucleated after injury. He thinks for the extension of the inflammatory process some other path must be sought than the nerves, and that that offered by the lymph spaces is the most probable one. Whether the micrococci be cause or consequence of the inflammation he does not undertake to decide, and sums up as follows: The hypothesis that sympathetic ophthalmia is explained by reflex action through the ciliary nerves is devoid of all convincing proofs. Sympathetic ophthalmia may be looked upon as proceeding from a septic choroiditis of definite type, not improbably resulting from an abnormal continuity between the external tissues and the uvea. The morbid changes of the vessels, the increase of lymphoid cells, and perhaps also, the accumulation of microphytoid organisms are the guiding signs that may indicate the direction in which the morbid process is propagated. The path of the transmission is most probably along the lymphatic spaces of the optic nerve.

#### A NEW PTOSIS OPERATION.

The insufficiency of operations hitherto proposed for the relief of complete or nearly complete ptosis, with little or no power in the levator, is well known. Pagenstecher<sup>2</sup> has devised an operation which depends for its effect on bringing the frontalis to act directly on the upper lid, and thus substituting the action of this muscle for that of the levator. This is accomplished by producing a superficial vertical cicatrix connecting the frontalis with the edge of the lid. A needle is entered about a finger's breadth above the supraorbital ridge and carried downward beneath the skin to emerge at the level of the lashes; a thread is drawn through, and the ends tied together without much dragging. Each day the thread is pulled on till it finally cuts its way out. The reaction is very moderate; the disfigurement caused by the scar is very little, and much more than made for up by the improvement in appearance obtained by relief of the ptosis. Pagenstecher has found one suture suffice in the cases operated on, but suggests that two may sometimes be necessary. For incomplete ptosis a modified form of procedure is advised. A thread armed with two needles is used. One needle is passed under the skin of the lid, parallel to and near the lashes, for a distance of one or two millimetres, drawn through, reentered at the point of exit, and carried upward beneath the skin to a finger's breadth above the supraorbital ridge. The other needle is then carried from the point where the first needle entered, also upward, to emerge at the same place as the first, above the brow. The two ends of the thread are drawn moderately tight and fastened. The loop thus formed may be removed after a longer

or shorter time, or allowed to cut itself through, according to the indications of the individual case, and in this way a wholly subcutaneous cicatricial cord is produced. Care should be taken not to sink the needles so deeply above the brow as to wound the periosteum, lest a connection between the skin and periosteum might occur and prevent movement of the vertical cord.

#### HYOSCINUM HYDRIODATUM AS A MYDRIATIC.

According to experiments of Emmert<sup>6</sup> on himself and others a drop of a one tenth per cent. solution of this drug acts on the pupil and accommodation more quickly and strongly than a drop of a one half per cent. solution of atropine; it also resists eserine for a time more than atropine does, but its effect is not so lasting. In cases of infiltration of the cornea, leucoma adhaerens, and various forms of iritis, in which neither a one half per cent. solution of atropine nor of eserine dilated the pupil or ruptured synechia, this result was brought about by the hyosine solution in a strength of one tenth to one half per cent. Slight and temporary toxic symptoms (dizziness or unsteadiness of gait) were frequently observed from its use, but no serious general disturbances. Generally a solution of one tenth per cent is sufficient, and this produces greater effect on the pupil than any other mydriatic known.

### Reports of Societies.

#### PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

BY W. H. RICHARDSON, M. D., SECRETARY.

REGULAR meeting November 21, 1881.

#### SPONGES FROM FARM POND.

DR. J. O. GREEN reported briefly the result of Professor Remsen's investigations into the cause of the bad taste of the Boston water, and showed specimens of the sponges taken from Farm Pond. These specimens were found after drawing off the water from the pond. They have the same taste and odor as the water as nearly as can be made out. The color is partly green, while some of the specimens are black from a deposit of mud. It grows attached to rocks, and is not found on the muddy or low part of the pond. The growth covers one fifth of the bottom of Farm Pond, and is found in masses one to two feet in length. It decomposes very rapidly, twenty-four hours causing it to rot completely. Professor Farlow pronounces it a true sponge, and not a vegetable growth.

DR. H. W. WILLIAMS asked if there was any theory to account for the existence of this growth in Farm Pond alone.

DR. GREEN said that Farm Pond had been for ages an old pond, and had been utilized for its water supply. He did not know when it had been drawn off before. Professor Remsen found nothing of the kind in Baltimore water. The growth was first discovered on the screens of the pond.

#### TREATMENT OF POSTERIOR HYPERTROPHY OF THE INFERIOR TURBINATED BONES.

DR. KNIGHT read a paper on this subject.

Among the most common causes of obstruction of the nares is hypertrophy of the turbinated bones, espe-

<sup>1</sup> Transactions of the International Medical Congress. London. 1881.

<sup>2</sup> Archiv für Augenheilkunde, xi. 2. Centralblatt für pract. Augenheilkunde, April, 1882.

cially the inferior. This is, strictly speaking, a hypertrophy of the mucous and submucous tissues and not of the bone itself. The removal of these hypertrophies constitutes one of the greatest advances yet made in the treatment of the affections of this region. The hypertrophy may involve the whole bone, or may occur on either the anterior or posterior portions. The symptoms produced by posterior hypertrophy are: (1.) Obstruction to nasal respiration. (2.) Difficulty of removing catarrhal secretion either by blowing the nose or by means of the douche or syringe. (3.) Serious modification of the voice, production of the obstructed quality usually improperly called nasal. (4.) Deafness either by direct pressure upon the orifice of the Eustachian tube or by keeping up the catarrhal condition in the neighborhood. (5.) Impairment of the sense of smell.

The only treatment which has proved at all efficacious for the removal of this condition has been such as would actually remove a considerable portion of the hypertrophied tissue, which is best done by the wire snare of Dr. Jarvis of New York.

The wire loop is passed through the nares and is adjusted in position by aid of the rhinoscopic mirror. On drawing the wire home the tissue is cleanly divided, and, if not too large to pass through the nares, it will generally be drawn out clinging to the snare. Traction should be made very slowly, stopping at short intervals, in order that the hæmorrhage may be as little as possible.

Several questions present themselves to one about to use the instrument for the first time. Is there any danger, after having engaged a mass of tissue in the loop, of being unable to complete the operation? There ought to be no difficulty of this kind, yet some gentlemen have found this difficulty, and their cases should be reported, in order that the least trouble may be recognized and guarded against. There is no more pain than a patient who has suffered obstruction will willingly endure for the sake of a cure. If an hour or two is consumed in the operation, the hæmorrhage is usually slight.

A case was reported to illustrate this method of treatment.

A teacher of singing had suffered from post-nasal catarrh and obstruction for three years. The sense of smell was lost. Various remedies had been prescribed for the relief of her symptoms. Lately the nasal obstruction has become so great as to seriously affect the quality of the voice. Examination of the posterior nares showed them completely blocked by swelling of the turbinated bones, especially the inferior. Radical treatment was imperative. Accordingly, the posterior portions of both turbinated bones were removed by Jarvis's snare at different sittings. The first operation was completed in twenty minutes, and there was considerable hæmorrhage. With the second operation more time was allowed. The relief to the breathing was immediate.

Dr. KNIGHT remarked, in answer to Dr. Wells, that this condition of the turbinated bones is quite common.

Dr. WHITNEY asked whether the reader had seen any preparations of the bones removed in these cases.

Dr. KNIGHT replied that he had found hypertrophy of the mucous and submucous tissue, with no change in the bone itself. The hypertrophy of the mucous membrane is the cause of the obstruction, and not any change in the bone itself.

Dr. WHITNEY said that the question had suggested itself to him while examining the skulls of mound builders, in which he found posterior hypertrophy of the turbinated bones. In one case there was pushing of the septum to one side. He wondered whether these people suffered from catarrh from this cause.

In reply to Dr. Shattuck, Dr. KNIGHT said that he thought it would not be necessary to repeat the operation, for there is a good deal of contraction of the part afterwards. There has not been, as yet, however, enough experience with the operation to say exactly. If only a little membrane is taken off the operation might have to be repeated.

Dr. HOOVER said that any one who had attempted this operation would appreciate the importance of the first step, namely, the application of the noose to the hypertrophied tissue, and of being sure that it is in proper position before tightening it. Although it is not difficult, in most cases, to adjust the noose properly, it is very easily displaced by a little unsteadiness on the part of the operator, or gagging of the patient. In one case the noose was in some manner dislodged, and subsequently became so imbedded that it was impossible to see its position. There ought to be some means of fixing the noose before tightening it. In the operation itself there is also difficulty. In cases where a deviation of the septum exists it is almost impossible to adjust the noose, especially where the deviation is anteriorly and towards the diseased side. Hæmorrhage may be a serious complication. At an operation a few days ago on a small boy, with complete occlusion of the posterior nares, removal of the right side was attended by no hæmorrhage at all. On the other side, however, there was considerable bleeding, though about the same time was taken for each side. Dr. Wynne says that by the finger he can assure himself of the condition of the Eustachian tube, fossa of Rosenmüller, the presence of polypi, or of an adventitious growth. Were it possible to put the finger back, and feel the position of the snare one great difficulty would be overcome. Dr. Hooper could feel the Eustachian tube with the finger, but could not reach either the septum or the turbinated bones. Dr. Wynne says it is a procedure which never fails, and which dispenses with the rhinoscopic mirror. Dr. Hooper did not see how this could be the case. On that morning he had found by measurement the distance from the septum naris to the outside of the lip to be in no case less than twelve centimetres, and in one fourteen.

Dr. LANGMAID said that only specialists know the agony and suffering caused the patient by occlusion of the posterior nares, reflex dyspnoea coming on suddenly, sometimes in violent paroxysms during sleep; alteration in the voice; then the pain in the forehead is sometimes tremendous, so that minute investigation into this disease is important from a humanitarian point of view. With regard to hæmorrhage during the operation, Dr. Langmaid said, quoting from Dr. Bosworth, this is sometimes alarming. In one instance the patient became exsanguine. The amount of bleeding depends on the time taken in cutting through the tissues. When prolonged to three hours there has been none. In operations of two hours the hæmorrhage has been considerable, and in some cases very dangerous. The old treatment was very ineffectual for this condition of hypertrophy. Strong chromic acid was used as a local application. In some cases where the hypertrophy was limited to the mucous membrane

or the mucous glands, one was constantly baffled. Certain conditions of the atmosphere would bring the whole trouble back again. With regard to the examination by the finger, this depends on the configuration of the pharynx, and on the distance from the velum to the posterior wall. In some cases it will be found very easy to slip the finger behind the soft palate, and make out a good deal, but in a large number of cases, according to his experience, the attempt to examine by the finger is very unsatisfactory.

DR. KNIGHT added, in regard to the respiration, that real attacks of spasmodic asthma are sometimes due to this condition of the turbinated bones, and may be completely relieved by the operation. Digital examination of the pharynx and posterior nares is sometimes necessary where we wish to ascertain the condition of parts which we cannot see, or where it is necessary to get information as to density, hardness, etc. It seems ridiculous to say that this method should supersede rhinoscopy. In making a digital examination at the hospital, putting the finger into the posterior nares caused a good deal of pain and hemorrhage for some time after. Though exceptional examinations may be made by the finger, rhinoscopy should be the rule.

In reply to Dr. Bowditch the reader said that in the case of a certain professional singer, where the obstruction in the nose altered the quality of the voice, it was very necessary to do something. As soon as part of the turbinated bones had been removed the voice became as good as ever.

DR. BROWN showed a diagram, and MR. FREDERICK TIBOR explained the ventilation of the new Children's Hospital.

### Recent Literature.

*Student's Manual of Diseases of the Skin.* L. DUNCAN BULKLEY, M. D. New York: G. P. Putnam's Sons. 1882.

The classification used, Dr. Bulkley's modification of Hebra's System, is a very good one, and the different diseases of the skin are considered in the order therein designated. The main defects of the book are caused by the endeavor to handle the etiology, diagnosis, prognosis, and treatment of one hundred and twenty odd diseases, in a little over twice the number of 16mo. pages. Pathology, the only basis of a correct understanding of dermatology, is conspicuous by its absence, and the small size of the book compels a lack of the minuteness and fullness of direction necessary to instruction. A useful chapter on diet and hygiene, useful in impressing upon the student the need of attention to these things, and a collection of various recipes conclude the book.

— An inquest has been held at Preston, England, on the body of a boy, aged ten. It was stated that the deceased was brought to the house of a dentist at Preston, to have some teeth extracted. Seven teeth were taken out, the lad being placed under the influence of nitrous oxide gas. While unconscious he changed color, put his hand to his throat, and died. It was afterwards found that one of the teeth had fallen into the windpipe and choked him. A verdict of "accidental death" was returned.

## Medical and Surgical Journal.

THURSDAY, JUNE 1, 1882.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year including postage.*

*All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.* HOUGHTON, MIFFLIN AND COMPANY,  
No. 4 PARK STREET, BOSTON, MASS.

### THE MEETING OF THE AMERICAN MEDICAL ASSOCIATION AT ST. PAUL.

THE approaching meeting of the American Medical Association at St. Paul, which will be held June 6th, 7th, 8th, and 9th, notwithstanding the time required and the length of the journey, offers many attractions, directly and indirectly, to Eastern physicians. The season of the year, following on the anxieties and labors of a winter's work, invites to a vacation, an invitation which the freshness and joyousness of nature in her spring dress warmly emphasizes. To reach the place of meeting, the traveler from the East traverses many States, and passes through many cities representing in agriculture, in manufactures, and in commerce the richest, the most prosperous, and the most rapidly developing portion of this continent. A section in which the visible realities of to-day serve merely to stimulate the imagination to speculate on the promises of a near future.

St. Paul itself, a town of over 40,000 inhabitants, is at once a picturesque and agreeable place of residence, and a most thriving centre of trade of one of the very largest and most rapidly growing States of the Union. A State, moreover, whose climate and soil, from the favorable effects of life within its borders upon certain classes of invalids, are of peculiar interest to the physician as well as to the farmer, the railroad manager, and the merchant.

At the conclusion of the meeting those who are able to prolong their vacation will find themselves very favorably situated for making acquaintance with the prairies, and visiting some of the remarkable natural curiosities and points of interest of the farther West—among which may be especially mentioned the valleys of the Yellowstone and Red Rivers; or if one wishes fine scenery and capital fishing at a somewhat less distance there remains the north shore of Lake Superior.

The railroads connecting Chicago and St. Paul, as well as those connecting the latter city with various points North, South, and West, offer peculiarly favorable rates of fares not only for delegates, but for members of their families accompanying them. For details our readers are referred to the announcement upon the last page of the JOURNAL, which supersedes that made in our issue of May 18th.

If any Eastern physician has ever contemplated going temporarily West, and we repeat Horace Greeley's advice to both old and young, now is the favor-

able moment, when the season of the year, the railroad ticket agents, and professional discussion all unite in one appeal.

## THE QUESTION OF MEDICAL ETHICS AT ST. PAUL.

THE NEW YORK STATE MEDICAL SOCIETY *versus* THE AMERICAN MEDICAL ASSOCIATION.

THE question of medical ethics will undoubtedly be brought up at the approaching meeting of the American Medical Association at St. Paul, apropos of the recent action of the New York State Medical Society, when, under the guidance of a small section of the profession in that State, the Society voted to sanction consultations on the part of its members with men pretending to practice medicine according to a dogma or system.

We expressed our views as to the wisdom and propriety of this step on the part of the New York Medical Society at the time it was taken, and are glad to find ourselves in accord with the great mass of intelligent and honorable physicians throughout the country and with nearly all the respectable representatives of the medical press of the country.

On another page will be found an extract showing what is thought of the action of New York by our professional brethren across the Atlantic, who have themselves been compelled lately to consider this question pretty carefully.

There is no occasion, therefore, to say more about the matter at the present time or to anticipate the course of discussion and action at St. Paul, although those who engineered the late legislation in the New York Society expressed themselves openly and boldly, we may even say lightly heartedly, as ready to "run the Empire State alone," apparently for "what she is worth!"

## DR. OLIVER WENDELL HOLMES ON MEDICAL HIGHWAYS AND BY-WAYS.

HAVING been led, though very reluctantly, to refer again editorially to the homoeopathic delusion, a delusion meriting from the profession at large neither persecution nor recognition, but simply to be ignored, or at the utmost ridiculed, we must call our readers' attention to the lecture on Medical Highways and By-Ways by Dr. Oliver Wendell Holmes, which we are fortunate enough to be able to publish to-day. In it wit and wisdom are happily blended, and, after an interval of forty years, the lecturer takes occasion to pay his compliments to homoeopathy in a way calculated to make even the judicious laugh, and not to cause the homoeopathist himself to wholly grieve. Dr. Holmes takes up and develops some points which we do not remember to have seen touched, and certainly not dwelt upon, before.

The regular practitioner, the honest but perhaps enthusiastic physician and scientist are reminded too of their limitations, in phrases which cut but carry

with them the healing of their own wounds. What surgeon will bear a grudge for the quotation

"There's a Divinity that shapes our ends,  
Rough hew them how we will!"

or what anatomist, physiologist, chemist, or pathologist but offers himself a willing victim to the Autocrat of the Breakfast Table, when, as a lecturer to students in medicine, which we all are, he reads them so fine a sentence as the following:—

"No, gentlemen, there is no exclusive *a priori* method which leads to the successful treatment of disease. You begin in the primrose paths of knowledge which are only preliminary to your real work. Anatomy is no more medicine than a child's dissected alphabet is literature. Physiology and chemistry throw gleams of light here and there on curative methods, but commonly lead their votaries far away from practice. Pathological anatomy teaches a great deal, but it is, after all, like inspecting what is left of the fireworks on the morning of the fifth of July. It is very pleasant to dissect a muscle, to make a precipitate, to watch a contracting heart, to study a translucent slice of a healthy or diseased organ. These pursuits, sisters of her who presides over health and disease, are the sirens that won over Agassiz and Huxley and Helmholtz to their flowery realms. But just as zoology, chemistry, physiology, histology, are not the science of medicine, so neither is the science of medicine the same thing as the art of healing. To go hastily from the library of old books and the laboratory of new experiments to the bedside of disease is imitating the presumption of those rash profligates who, as Thomas Boston says, think they can take a 'leap out of Delilah's lap into Abraham's bosom.'"

## THE NEW ANTISEPTIC, BORO-GLYCERIDE, IN OPERATIVE SURGERY.

IN the issue of the JOURNAL for May 4th we gave a short account of a new antiseptic compound, boro-glyceride [ $C_2 H_5 Bo_2$ ], lately brought to the notice of the Society of Arts, of London, upon whose members its practical value evidently made a very favorable impression. The inventor and manufacturer, Professor Barff, has, if we are correctly informed, been experimenting with this compound, and perfecting it for commercial purposes for some years, but we had never heard of its being tested in operative surgery, and in our notice of May 4th, considering its qualities as a tasteless, inodorous, non-irritating, inexpensive antiseptic, we suggested its marked appropriateness for such an application. It was with especial interest, therefore, that we read a short paper on Boro-Glyceride in Operative Surgery in the *Lancet* [May 13th], by Mr. Richard Barwell, senior surgeon to Charing Cross Hospital.

Mr. Barwell states that, like many other surgeons, he had for some time past become dissatisfied with carbolic acid in various forms of wounds, and had also grown skeptical as to the alleged value of the spray. Although previous experiments which he had made with boracic acid had failed, he determined, after Pro-

fessor Barff's lecture before the Society of Arts, early in April, to try the boro-glyceride, attributing, as he did, his former failures with the pure acid to its insolubility, a difficulty removed by the new compound.

He accordingly tried the sample which he obtained from Professor Barff in three very different surgical cases, all well calculated to test the antiseptic value and general effects of the new compound as compared with carbolic acid. The report of the cases and the conclusions drawn from them by the operator are given below in Mr. Barwell's own words:—

**CASE I.** Edmund B., aged nineteen, came under my care in Charling Cross Hospital on April 18, 1882, with a large abscess over the lower right ribs. It appeared to have no connection with either the pleural cavity or the liver. On April 21st I made an incision about an inch and a half long, and let out five ounces of pus. A good deal still remained, for the abscess was not squeezed. Passing in my finger, I found about two inches or two inches and a half of a rib bare, and the upper border of the next lower rib was also denuded to the extent of about an inch. Having ascertained these particulars, I injected the abscess with a watery solution of the boro-glyceride (one in twenty), passed in a drainage tube, covered the opening with four folds of lint steeped in the same fluid, and with a piece of thin mackintosh, securing the whole with a bandage. On the next day, and for ten days, the temperature was normal. May 2d. The temperature rose to 99.2° F. last night. I passed my finger into the wound, and could find no portion of bone bare; that which had been so had apparently become covered by granulations. Temperature 100° F. May 3d. Temperature 102.1° F.; bowels confined. An aperient was ordered. May 4th. Temperature normal. May 8th. Wound all but well.

**CASE II.** James H., aged forty-four, had been for the second time a week or two in hospital, that the cause of pyelitis, hamaturia, and pain in the right loin might be made out. After several consultations with Dr. Bruce, Dr. Colquhoun, and Mr. Morgan, it was agreed that my duty was to explore the kidney. May 4th. I cut down through the right loin to the kidney; hardly any blood was lost; no stone could be detected. Behind the gland was a very unusual amount of fat, a small quantity of which, as it was in the way, was removed. The wound was thoroughly sponged out with a five per cent. solution of boro-glyceride, and sewn up close except about half an inch at the lower end, no drainage tube being introduced. The dressing was simply a fourfold pledget of lint, steeped in the same solution, and covered with thin mackintosh. That night the temperature was 103.4° F. May 5th. The man complained of cough, sore throat, and some headache. Tongue a little furred. Temperature: morning 102.4° F.; evening 103.4° F. An aperient was ordered. May 6th. Still some cough. Temperature: morning 100° F.; evening 100.9° F. May 7th. Temperature: morning 99.4° F.; evening 99° F. Wound perfectly healthy. No redness or swelling, even the edges free from any sign of irritation. At the lower end, which had purposely been left a little open, the tissues beneath were red and fresh looking. There was no trace or sign of pus. May 8th. Temperature: morning 98.6° F. May 9th. Temperature: morning 98.6° F.; evening 100.2° F.

**CASE III.** William L., aged twenty-nine, was under my care for political anaemia. Pressure had failed, and therefore I determined on deligation. May 4th. After dividing the superficial fascia, and turning aside the saphena vein which overlay it, the artery was easily reached, and tied with ox aorta ligature. The wound was filled and sponged with the solution of boro-glyceride, sewn and dressed with pledgets soaked in the same solution. Since the operation there has been no pain and no return of pulsation. The wound has been absolutely painless; it was dressed on the fifth day; it looked perfectly quiescent, and was all but healed. The thermometer has ranged thus:—

|             | Morning. | Evening. |             | Morning. | Evening. |
|-------------|----------|----------|-------------|----------|----------|
| May 4th . . | —        | 98.6°    | May 7th . . | 98.5°    | 99.0°    |
| May 5th . . | 98.6°    | 100.0°   | May 8th . . | 98.5°    | 99.4°    |
| May 6th . . | 98.6°    | 99.6°    | May 9th . . | 98.6°    | 99.2°    |

When these cases are considered it will be observed that in two of them a certain rise of temperature occurred; evidently in neither case was this due to septicæmia. In Case I, it was too late, as also too transient, being removed by a purgative. In Case II, it was too early, occurring six hours after operation; it was probably due to irritation of the kidney, and in part to catarrh, which may have been produced by exposure during operation; it, too, was transient, a purgative hastening its disappearance. In Case III, there was no rise of any significance. In Case I, the large abscess of the side was especially calculated to test the value of this material. Such an abscess, if opened and left unprotected, almost certainly causes pyrexia. If carbolic acid had been used I consider that the ribs would not have become covered with granulations, certainly not in the time. On the contrary, necrosis would probably have occurred. Moreover, to impregnate the walls of so large a cavity with carbolic acid would not have been void of danger. In the third case—the only one of mere wound uncomplicated by any additional possibilities of pyrexia—we have the most perfect act of healing I have ever seen.

Although three cases may be a small number from which to generalize, yet having regard to the diversity in character of those just reported, I think we may conclude that we have in the boro-glyceride an aseptic for wounds safer and less irritating locally than carbolic acid, free also from the danger of constitutional poisoning. It may be that I have not hit on the best strength of solution for the dressing, and certainly some other diluent besides water will be desirable. I am now making experiments in that direction. Nothing, however, can be better than the action of this compound. The intricate and not very safe complications of carbolic treatment—the spray and all the inconveniences belonging to it—may now be laid aside. The method which I introduce is exceedingly simple; in using it it is only necessary to place on the washed and sewn wound a few folds of lint soaked in the solution, to cover them with thin mackintosh, and to secure them with a bandage. Under such dressing healing takes place in the most beautiful and perfect manner.

#### MEDICAL NOTES.

—A reader has called our attention to the fact that although Koch's announcement of his discovery of the bacillus of tuberculosis was noticed editorially in our issue of April 20th, an esteemed contemporary in Philadelphia, which first mentioned the subject April 29th, has been taking credit to itself for its enterprise in having been the first American journal to make the subject public.

—We understand the Prussian authorities still propose to hold the Sanitary Exposition at Berlin in June notwithstanding the unfortunate conflagration some weeks since, which destroyed both the building and many of the articles for exhibition already forwarded.

#### NEW YORK.

—At the instance of a number of prominent medical men the visiting staff of Bellevue Hospital has lately been reorganized by the Commissioners of Charities and Correction. For some years past it has been thought in certain circles of the profession that Bellevue College received the lion's share of the appointments, and this has given rise at times to considerable ill-feeling and unfavorable comment. In the present distribution of places, therefore, an effort has been made to satisfy all parties, so far as was possible, by allowing the authorities of each of the three large medical schools to select an equal number of physicians and surgeons connected with each for service at the hospital. The new board is constituted as follows: Representatives of Bellevue Hospital Medical College: Physicians, — Austin Flint, Jr., E. G. Jane-

way, and A. A. Smith; Surgeons, — E. L. Keyes, J. D. Bryant, and F. L. Dennis; Gynaecologist, — W. T. Lusk. Representatives of the College of Physicians and Surgeons: Physicians, — Alonzo Clark, Francis Delafield, and Abram Jacobi; Surgeons, — R. F. Weir, Charles McBurney and T. T. Sabine; Gynaecologist, — George L. Peabody. Representatives of the University Medical College: Physicians, — Alfred L. Loomis, William H. Thomson, and F. R. S. Drake; Surgeons, — Stephen Smith, L. A. Stinson, and J. W. Wright; Gynaecologist, — William M. Polk. Non-Collegiate Class: Physicians, — James W. Williams, W. Gill Wylie, and Henry F. Walker; Surgeons, — J. W. S. Gouley, William C. Hunter, and Frederick Lange; Gynaecologist, — Walter R. Gillette. By the new arrangement four members of the old board are dropped, and Drs. Lewis A. Sayre and Alexander B. Mott are added to the consulting board. The name of Dr. Stephen Smith, it will be noticed, appears as a representative of the University Medical School. Although in common with the other members of the Post-graduate Faculty he handed in his resignation, subject to the approval of the regular Faculty, it seems that he did not join with the other gentlemen in demanding afterwards that the resignation should be accepted at once, and that since then he has been induced to retain the chair of orthopedic surgery in the college. This is the first time in the history of Bellevue Hospital that gentlemen have been distinctly appointed as gynaecologists in it, (although special attention to gynaecological practice has long been paid by several of the members of the medical board), and this department is now intended to embrace also that of diseases of children. As heretofore, Dr. Jacobi will probably have the principal charge of the children's wards, and in order that this arrangement may be carried out it is thought that he will change places in the board with Dr. Peabody. Among the regulations adopted at the time of the reorganization of the board are the following: Whenever a vacancy occurs in the representation of any college it is to be filled by a candidate nominated by the college and appointed by the Commissioners of Charities and Correction, who will consider no nomination except from that college. Vacancies in the non-collegiate class shall be filled from physicians and surgeons who are not connected with either of the three colleges represented in the medical board, by the commissioners or nominated by the medical board of the hospital. The services of the hospital shall be divided as nearly as possible into four equal parts, which shall be assigned, one for each, to the four classes of physicians and surgeons. The medical board shall have no power to restrict or interfere in any way with the clinical lectures in the hospital, and each college shall have the right to retain the same hours for clinical lectures which it has used for the past year. Each college represented in the medical board shall be entitled to nominate for appointment by the Commissioners, after competitive examination in such college, its proportion of members of the house staff of the hospital; such members to be attached to the division belonging to the college mak-

ing such nominations. The non-collegiate class shall be entitled to nominate for appointment by the Commissioners, after competitive examination by itself, its proportion of members of the house staff; such members to be attached to the non-collegiate division of the hospital. The new board held their first meeting on the 15th of May, when Dr. Alonzo Clark was elected president, and Dr. George L. Peabody secretary of the board, and the various terms of service were assigned.

It is said that some of the older Bellevue College men are not altogether satisfied with the new arrangement. They claim that it was the teachers of their school that gave the hospital all its reputation as a field for clinical study, and that the college is therefore legitimately entitled to a larger representation in the medical board than either of the others.

#### CHICAGO.

— Dr. Isaac N. Danforth having lately resigned his position as professor of pathological histology in Rush College, has been appointed professor of clinical medicine and renal diseases in the Chicago Medical College. Dr. Christian Denger has been made professor of general pathology, and Dr. F. C. Schaffer has become professor of anatomy in the same institution.

— Dr. E. S. Jenks has resigned the professorship of gynaecology in the Chicago Medical College, and Dr. E. C. Dudley has been appointed in his stead.

#### PHARMACEUTICAL NOTE.

— Chlorate of soda, which is now to be found in most pharmacies, is recommended to be used instead of the potash salt, on account of being very much more soluble. At the ordinary temperature, while the one requires sixteen parts of water the other requires but one, and in alcoholic solutions but about thirty parts instead of about one hundred and twenty parts. This last fact is of especial importance when it is to be used in conjunction with tincture ferri chloridi, as it now so often is, in the treatment of diphtheria. The salt has, however, the disadvantage of being somewhat deliquescent.

#### Miscellany.

##### PETITION FOR A STAY OF PROCEEDINGS IN THE CASE OF GUTEAU.

MR. EDITOR, — Your editorial on Guiteau and the petition for a stay of proceedings, in your issue of May 18th, was written so carefully, and contains so much of truth, that, by your permission, I will briefly reply to one or two statements with which I cannot agree. The general question, whether the insane can be legally punished, I propose to answer, in some detail, in a work on the Psychology of Salem Witchcraft, now in press.

The special points to be met just now are these: —

(1.) You say that, inasmuch as Guiteau has been unjustly condemned, society should now have the ben-

effit of the doubt; that the trial which you properly characterize as disgraceful, and a verdict which — from your point of view and mine — is unjust, should be supplemented by hanging; in a word, that one injustice can be corrected by another injustice; that although it was wrong to even try Guiteau, it is right to hang him.

The benefit of a doubt belongs to the accused, not only before and during the trial, but after a verdict, and after a succession of verdicts, and up to and after execution; through all time, hanged or unhanged, Guiteau must be held to be presumably insane.

It was by this benefit of doubt that Cadet Whittaker — with whose case I was professionally connected — lately obtained in Washington, after two unjust verdicts, contrary to the evidence, substantial though tardy vindication.

In the case of Guiteau the interference of the profession is needed now more than ever before. Says your neighbor Lowell: —

"Then to side with truth is noble, when you share its wretched crust."

Of the large number of authorities on the nervous system who have lately published the opinion that Guiteau was insane, only a fraction testified on the trial. Casting aside all the opinions in favor of his insanity presented on the trial, and all others that have since been published by others and myself as of no value, *there has appeared in your journal alone adequate quality and sufficient quantity of evidence for the defense to have saved the assassin from the scaffold, had the case been only one of ordinary interest.*

No lunatic ever hauled before a court in this country, or any other country, so far as I can learn, has ever obtained so much expert testimony of a high order in favor of his insanity as has Guiteau. In making this statement I count my own opinions for naught. If the result of this protest of the profession shall be the substitution of permanent confinement for life for the halter, practical justice will have been gained. Whether the experts that the President should appoint should agree or not is of no moment.

(2.) You say that Guiteau, though insane, is less insane than the evidence seemed to make him.

Some of the worst diseases have no pathology; the type of insanity which, as we all agree, Guiteau represents, has no important physical symptoms that the senses can discover. What cannot be seen, or felt, or heard, the non-expert and non-disciplined mind doubts or denies. A post-mortem examination will probably find nothing in Guiteau's brain to account for his insanity, and yet his craziness is of a terrible and incurable character. It took eight generations of clergymen to make an Emerson; it took, perhaps, half as many generations of philosophers and scholars to make a Darwin; it took, we know not how many generations of fanaticism and degeneration to produce, by the law of the escape of the weakest, a Guiteau; but in this waste product, cast off in the evolution of the race, insanity is organized as firmly as Darwin's science or Emerson's poetry.

Although insanity is a disease of degree, yet such a disease as *mild* insanity has never existed, can never exist, and the popular belief in its existence is as truly a mistake as the belief in witchcraft. By a single delusion the rich and delicate fabric of the mind may be rent in twain beyond repair; a gun cannot burst a little; a single crack is ruin.

(3.) You say that "the assassin has little claim upon the interest or sympathy of the community."

This is quite true; it is quite as true of nearly all assassins and of thousands upon thousands of our fellow beings, sane and insane. Shall we, therefore, slaughter them all to-morrow? Insanity is always a disgusting disease; our first impulse in dealing with lunatics is to knock them down. What is done to Guiteau is of no account; what we do, or allow to be done to him is of all account. Guiteau is as ready for the scaffold as for his breakfast; but is it, therefore, all the same whether we hang him or feed him?

Says Mr. Seward in his defense of the insane negro Freeman: "The execution of a madman is murder." . . . "I am the lawyer for society." Psychology does not plead for Guiteau, but for his would-be murderers. The sufferers from the Salem witchcraft excitement in 1692 were not the twenty victims, but the survivors and their descendants and descendant's descendants, to this hour.

(4.) It may be said, it has been said, that America is the non-expert's land; that the mob will have its way, and that the profession can do little; but for this reason it should do that little. Mobs are not authorities in psychology, and are not to be cruelly censured for their ignorance or even for their passion; but we are to be censured and shall be censured by posterity, — the verdict of which is as sure as the future — for not at least trying to save the mob from itself. Experts are the guardians of non-experts, and in a degree responsible for them, like parents for children.

The conduct of our profession in its relation to these popular delusions is a line of darkness and of blood in our history for more than two hundred years. In Salem it was a physician who mistook the symptoms of nervous disease for the symptoms of possession of the devil, and so started and stimulated the witchcraft trials and executions; in Auburn a physician testified that the demented Freeman, whom Seward defended, was responsible; at West Point it was a physician who declared that the unconscious cadet Whittaker was feigning and conscious; in Washington, what you call "those disgraceful three months," were slightly redeemed by the fact that, for almost the first time in our history, a few authorities in psychology testified against the unanimous opposition of the nation.

If, as has been said of Salem, "the pathway through the court must lead to gallows hill;" if Guiteau is to pay on the scaffold the penalty of his countrymen's non-expertness in psychology; if the principle of expiation is to be transferred from theology to law, and the sins of our people in so often acquitting the sane on the insanity plea are so numerous that only the blood of a lunatic can wash them away; if on this one has the lot fallen to be the last important insane murderer to be himself murdered, as the twenty victims of the witchcraft excitement were about the last who suffered for the imaginary crime, then it will be something to be able to say for this time and for all time, that there were a few at least who, from the first, and with all the force of their natures, consistently and persistently protested against the trial, and that up to the last moment the representatives of American psychology, to whom alone the question belongs, were not unanimously consenting to that colossal crime.

Yours truly,

GEORGE M. BEARD.

NEW YORK, May 20.

## MEDICAL ETHICS IN NEW YORK.

THE New York State Medical Society has taken Medical Ethics into its own hands, and has passed a law that sanctions consultation with any person holding a legal qualification to practice—that is to say, with eclectics, homœopaths, etc.—so long as they are licensed. This idea is not original; it will be remembered by our readers in connection with the addresses of Dr. Bristowe and Mr. Jonathan Hutchinson at the Ryde meeting. These gentlemen knew the sentiment of the profession too well to put the idea into the form of a rule of ethics or of practice. But the New York State Medical Society is more bold, and has passed the law. But it has reckoned without its host. The whole feeling of the profession in the States is against the step taken by the Society, unless it be some New York medical papers, which we may assume to be under the guidance of those who lead the Society. We need not say that the law is against the code of the American Medical Association, which, while enjoining all reasonable liberality in meeting intelligent regular practitioners that will be acceptable to the patient, adds—*“but no one can be considered as a regular practitioner or a fit associate in consultation whose practice is based on an exclusive dogma, to the rejection of the accumulated experience of the profession and of the aids actually furnished by anatomy, physiology, pathology, and organic chemistry.”*

This is the language of common sense and of loyalty to science, and evidently expresses the feeling of the profession in America, as it does that of the profession here. It is important to notice the fundamental error at the root of the Regulation of the New York Society. It assumes that the mere qualification to practice is a guaranty of everything necessary; as if there were no need for a code of ethical principles between medical men. This is a great mistake. The standing of the profession in society and the respect in which it is held by the nations have their explanation as much in the high character of the ethical principles by which the conduct of its members is regulated as in the intellectual and scientific nature of their calling. A great part of medical ethics has always had reference to the mutual relations and obligations of medical men. So that the mere fact of men being equally qualified in the eye of the law does not dispose of the moral questions which arise in practice, one of which is the amount of respect due to those who assume the truth of exclusive dogmas, and swear by one teacher, to say nothing of the absurdity of the dogma and the discredit of the teacher. Our law very properly provides that the holding of any particular theory of medicine by a candidate shall not entitle an examining board to reject him. In free countries men must be allowed to believe things which to most of their fellows seem absurd. But that is no reason why the bulk of the profession should not act in defense of its dignity, or why they should not be at liberty to decline professional consultation with those who would lower the tone of medical science. Rather is it the very reason why medical societies should do what it is scarcely to be expected that the common law should undertake. We are assuming that the case is clear, that the shibboleth adopted is something inconsistent with the broad light of medical experience and common sense. This is the case of homœopathy, which is practiced in its purity now by scarcely any of those who trade upon

the word, and yet which is nothing if it is not exclusive. Its chief disciples have shown a readiness to abandon everything but the name, which has a sort of trade value among a certain section of the public. Such being the discreditable position of homœopathy, we do not wonder that the professional opinion of the United States is strongly against the action and the ethics of the New York Medical Society.—*London Lancet.*

## LETTER FROM VIENNA.

## CÆSAREAN SECTION.

VIENNA, March, 1882.

MR. EDITOR,—A brief account of a Cæsarean section recently performed by Professor Spaeth may not be uninteresting to the readers of the JOURNAL.

The patient, twenty-one years old, had a narrow pelvis, the conjugate diameter of which measured six centimetres, and the outlet only three centimetres. The operation was performed according to the method of Porro, the chief object of which is to avoid the danger of infection from the collection of the secretions of the uterus in the abdominal cavity, which takes place during and after the old-fashioned operation. This is accomplished by the complete extirpation of the uterus and its appendages.

The abdominal incision, commencing four or five centimetres above the umbilicus, was extended to the symphysis pubis. The whole uterus was then turned out of the abdominal cavity, and a clamp applied as far down on the cervix as possible; all circulation to and from the uterus being thus cut off, a longitudinal incision into the body of the uterus was made as quickly as possible, and the child extracted. The uterus was then amputated at a point just above the clamp, and the stump fastened to the edges of the abdominal incision, the clamp being left, of course, in situ. The wound was dressed with iodoform. The patient has done uninterruptedly well, the temperature varying between 36° and 37.6° C. The clamp was removed on the tenth day, and now—twentieth day—the stump presents a granulating surface. The child is also doing well.

Schroeder says, “If the conjugate measures less than six and a half centimetres, all hope of delivering a living child by the natural way must be given up, and the only substitute is the ‘Kaiserschnitt.’” He considers it a much better operation than craniotomy, and that it is to be preferred even with a dead child in a very narrow pelvis. In Germany five and a half centimetres is the limit for craniotomy; Barnes, however, thinks it can be successfully performed with only a diameter of two and three quarters centimetres.

It is thought that this operation of Porro, through its more favorable results, has or will, replace the ordinary operation of sectio Cæsarea,—there are cases though where it is not indicated; notably, one at present in Professor Spaeth's wards, the patient still carrying a living child, having extensive carcinomatous infiltration of the cervix uteri. The disease has so completely involved the cervix, that removal of the growth, with safety to the mother, is out of the question; and delivering by forceps or turning cannot be considered. Here the ordinary operation is alone justifiable, since the life of the child is of more importance than the already surely lost life of the mother.

## REPORTED MORTALITY FOR THE WEEK ENDING MAY 20, 1882.

### AMERICAN MEDICAL ASSOCIATION.

In anticipating the meeting of the American Medical Association in this city on the 6th, 7th, 8th, and 9th of June prox., the Committee of Arrangements have secured the following rates from the various railroads centering at this point:—

The Chicago, Milwaukee, and St. Paul R. R. offers a rate of \$12.50 for a round-trip ticket from Chicago to St. Paul and return to delegates and ladies accompanying them upon presentation of credentials at general or depot offices in Chicago; also return tickets to all points this side of Chicago for one fifth fare, on certificate from the chairman of the Committee of Arrangements.

The Chicago, St. Paul, Minneapolis and Omaha offer the same rates from Chicago and all points between Chicago and St. Paul, also from Sioux City and all points north. From Omaha and all points south, two cents a mile for round-trip tickets.

The Minneapolis and St. Louis R. R. offer the same rates (\$12.50) from Chicago to St. Paul and return via the Chicago, Rock Island, and Pacific R. R., and at a rate of \$18.00 from St. Louis to St. Paul and return, *via* St. Louis, Chicago, Burlington, and Quincy R. R. (*via* Albert Lea). Also one fifth fare returning to all intermediate points.

All tickets on above roads good till July 10th.

The St. Paul, Minneapolis, and Manitoba R. R. will give passes to every delegate and to ladies accompanying them, over all divisions of its road, good for the entire month of June. Their road runs through the celebrated Red River Valley and the great wheat farms to Winnipeg. It connects Minneapolis and Lake Minnetonka (the largest watering place in the State, with four large hotels) with St. Paul.

The Northern Pacific R. R. will return all delegates for one fifth fare, and offers free transportation for the month of June to delegates and ladies accompanying them to the Yellowstone Valley and return.

The St. Paul and Duluth R. R. offers free passes to delegates and ladies accompanying them, over their line to Duluth on the north shore of Lake Superior and return.

The two lines of river packets, namely, the St. Paul and St. Louis Packet Co., and the Diamond Jo line offer one half transportation rates from all points to or from St. Paul. (They charge full rates for berths and meals.)

The Lake Superior Transit Co. offer the following rates:—

|  |          |
|--|----------|
| Buffalo to St. Paul, one way, . . . . .      | \$27.10. |
| Buffalo to St. Paul, round trip, . . . . .   | 47.20.   |
| Eric to St. Paul, one way, . . . . .         | 25.10.   |
| Eric to St. Paul, round trip, . . . . .      | 45.60.   |
| Cleveland to St. Paul, one way, . . . . .    | 23.75.   |
| Cleveland to St. Paul, round trip, . . . . . | 39.20.   |
| Detroit to St. Paul, one way, . . . . .      | 21.20.   |
| Detroit to St. Paul, round trip, . . . . .   | 35.20.   |

Meals and state rooms on steamers are included in the above rates.

The above company have also offered a complimentary excursion

sion down the lake and return, from Duluth, one day immediately after the meeting.

The hotels of St. Paul are the "Merchants" (\$3 to \$3.50); "Metropolitan" (\$3 to \$3.50); "Wind-or" (\$2.50); "Clarendon" (\$2.50); "Sherman" (\$2.50); "International" (\$2.00); "St. James" (\$2.00); and "Commercial" (\$2.00). The first three are provided with elevators.

The Opera House, in which the general session will be held, seats a thousand persons.

Minneapolis, a city of sixty thousand, lies nine miles from St. Paul, on the line of the St. Paul, Minneapolis, and Manitoba road, and has fine hotel accommodations. Half-hourly trains connect the two cities. Trains run almost hourly to and from Lake Minnetonka. Very respectfully,

ALEX. J. STONE, Chm. Com. Arrangements.  
ST. PAUL, MINNESOTA, May 12, 1882.

### OTOLOGY AT THE BRITISH MEDICAL ASSOCIATION. FIFTIETH ANNUAL MEETING.

HITHERTO at the meetings of the British Medical Association Otolology has been classed merely as a sub-section of Surgery. At the next annual meeting, however, to be held at Worcester on the 8th, 9th, 10th, and 11th of August, 1882, a whole section will be devoted to Diseases of the Ear.

To contribute to the success of the new section papers upon otological subjects are requested, and it is necessary that the undersigned, secretaries of the section, should be made acquainted with the titles of papers to be read not later than the 23d of June, and that short abstracts should be forwarded not later than the 15th of July, addressed to the undersigned at 20 Alva Street, Edinburgh.

J. J. KIRK DUNCANSON.  
P. McBRIDE.

RESIGNATION.—Dr. Thomas Waterman has resigned his position as Assistant in Anatomy in the Harvard Medical School.

BOOKS AND PAMPHLETS RECEIVED.—*Materia Medica and Therapeutics. Inorganic Substances.* By Charles D. F. Phillips, M. D., late Lecturer on Materia Medica and Therapeutics at the Westminster Hospital Medical School. Edited and adapted to the United States Pharmacopoeia. By Laurence Johnson, A. M., M. D. Vol. I. New York: William Wood & Co. 1882. (Wood's Library of Standard Medical Authors. Volume for April.)

*A Manual of Obstetrics.* By A. F. A. King, M. D., Professor of Obstetrics and Diseases of Women and Children in the Medical Department of the Columbian University, Washington, D. C. With forty-eight illustrations. Philadelphia: Henry C. Lea's Son & Co. 1882. (A. Williams & Co.)

Annual Report of the Board of Regents of the Smithsonian Institution, showing the Operations, Expenditures, and Condition of the Institution for the Year 1880. Washington. 1881.

## Lectures.

### THE MAN AS DOCTOR.

AN ORATION DELIVERED AT THE ANNUAL MEETING  
OF THE SOUTH MIDDLESEX MEDICAL SOCIETY,  
APRIL 19, 1882.

BY EDWARD WALDO EMERSON, M. D.

THE learned Professor Meynert, of Vienna, I have been told by one of his pupils, after years spent with patience well nigh past belief in unraveling the complex, matted nerve fibres, and tracing them to their origins in the encephalon, came to this belief: that thought and action were mere reflex phenomena, automatic results of the data, namely, the outward circumstances and the given quality and arrangement of the ganglia and fibres; in short, that free will was not. If, then, fate rules our every act, not, as the Greek thought, from afar, but seated in the very brain, with short hold on the bridle, those subtle white reins that we cannot choose but obey, to inspect ourselves were but an idle amusement. Yet surely this zealous Austrian worker in ordinary moments cannot but feel that *he* chooses and decides, and we, the ninety and nine that have not come to this view, please ourselves rightly or wrongly with the belief that while we are influenced by wind and currents, and even the variation of the compass, and the tricks played by the mirage with the coast and sea-marks, yet that *we* stand at the helm, and may change our course, or even put the ship about at will. Hence it has seemed to me worth while to consider how far we, as men, are changed, by becoming doctors, for good or for ill, and this is the matter which I venture to bring before you, my colleagues, to-day.

The man who has practiced but a few years will hardly make question of the fact that he is other than he can believe he would have been had he surveyed lands, engaged in trade, or modeled statues. It is surely well to look to it what manner of man he is becoming. Granted that the personal equation controls the result, may not the influences of the profession, minutely varying, be broadly viewed as a constant? These silent forces that do what they may with the doctor, constant comrades in his chaise, at his elbow, by the bedside or operating-table, punctual messmates at the family board, of what kind are they? Like the fair and swarthy riders that join the huntsman in Bürger's wild ballad, they, though manifold, work either for or against his larger hopes and interests. They work on all his faculties, intellectual, spiritual, physical, with power to loose or to bind.

If, now, we accept for this whole triple human structure the usual statement with regard to its physical element, that absolute health there is none, only coarse and transient approximations to balance in the ever-flowing and ebbing processes, yet all that tends to preserve the nicest equilibrium in morals and intellect that the fineness of our perceptions will allow us to get is worth the striving for. A rocking boat is worth a hundred capsize ones.

The doctor's patients often pity him, — he sometimes pities himself, — for leading a life so irregular, so anxious, so exposed. We all know that these words describe the life, and yet physicians, as a class, are healthy and cheerful men. Varied activity, the meeting decidedly more trusting and grateful faces than hostile

ones, the washing out the last dismal or irritating impression with what oxygen is to be met in riding three miles against a stiff nor'wester, these help to keep him sound. Experience rapidly teaches him that if he would be a shining example of the survival of the fittest he must feed his engines well. The north wind will keep the draughts clear, and also teach him to diminish radiation and store up heat by wearing two coats. The stout and canny Major Dugally Dalgetty spoke for us, as well as for soldiers, when he said that "it was the duty of every commander of a fortress, on all occasions which offer, to secure as much munitions and vivres as his magazines can possibly hold, not knowing when they may have to sustain a siege or blockade." It is our constant reproach that we do as we wouldn't let others do. Very good, my blanched and nervous friend, but if you will live my life for six months you will be in condition to eat pie and drink coffee and sleep sound after them, hiding them "tight it out among themselves." As Thoreau said to the clergyman who reproved him for Sabbath-breaking, relating the dire mishaps that he had known to befall such offenders, "They forget that it is their own guilty consciences that trip them up, and not the Lord."

Among the faculties of the mind called for and strengthened by daily use in our profession stands rightly first, observation. Here lies the sick man with urgent trouble; what he says may be entirely misleading; the friends stand around, anxious spectators; we are called into the sick-room as if into the arena; time presses; the stakes are the patient's comfort and safety, the family's peace of mind, our own reputation. We learn to note rapidly in this delicate machine the evidences of broken springs, or only broken wheels, clogging dust that can be removed, deep rust, or a whole structure worn out past repair. Next, the most careless person who lives by our craft must of necessity learn method in his examination in mercy to himself, if not to the patient. One of the best instructions to a medical class that I remember was that of the late Dr. Edward Dalton, who said, "After careful and repeated auscultation, percussion, palpation, and even succussion of the patient for twenty minutes, you may not be very tired. He is."

The winnowing out the mass of worthless evidence that the patient and his friends throw in with what is really valuable, the balancing the indications for exercise against the need of rest, the decision whether to give the potent drug that has its clear danger, but may turn the wavering scale of life, the making up the mind how much of the dismal truth to speak out or withhold, — from these duties comes the formation of the judicial habit in our minds. That court must hold hourly session. Rash though we be, we learn to put on, piece by piece, the armor of caution. A learned and philanthropic lady once, in my hearing, pushed a philosopher hard to admit that the teaching of Socrates, of whom he was discoursing, really sanctioned the Kindergarten scheme, of which she was an apostle. "Possibly, partially," was his reply. He was a physician and had learned to keep his rear open.

The generalizing power and keen sight that recognizes in the particular case merely a cunningly muffled member of a well-known band of cut-throats is a brilliant gift that experience may bring us. But all the conditions must be observed if we would not, in striving for this, do injustice to our patients and ourselves. We must try not to be dazzled, then, by the

tale that the bystander so often tells, *apropos* of the careful examination we are making, of some old doctor, in a remote part of Maine, "probably you've heard tell of him," who, the instant he entered the door of the sick-room, would say, "That man 's got rheumatism of the stomach and won't live but just two hours," and he did n't.

What spiritual gifts has the demi-god *Æsculapius* for his sons? It has been said that cowardice is ignorance. Imagination holds up her mirror and doubles the terror. Now our privilege is to become familiar with the worst forms that frighten the race; to learn what we can do, and what cannot be done. It is no mean blessing to know our limitations, the *thus far* where our responsibility ends. Cowards will not remain cowards if they survive being driven to stand at bay once or twice. Our profession is a daily school of bravery of a certain sort. The watchword in a rude old ballad,

"Make courage for life to be capitaine chief,"

might well be ours. The courage of *Fabius the Delayer* is as often called for as that of *Scipio the Sword of Rome*. By hard lessons we are all taught, in some sort, promptness, decision and self-reliance. The necessity of keeping at least an outward show of cheerfulness is good and helps to form a habit of philosophic cheer under stormy skies.

Tonic to the physician's moral fibre is the duty of keeping sacred the confidences of his patients, an astringent tonic puckering up his mouth, perhaps.

The well-known reproach of an earlier age, disclaimed in the sixteenth century by our kindly and quaint brother, Sir Thomas Brown, "*Ubi tres medici, ibi duo athei*," may, perhaps, be thought nearer the truth for our day than for his; but atheism, in any proper sense, will seldom be the goal reached by the man before whose eyes the mysterious sacraments of birth and of death and all sad and tender relations of humanity daily occur, or who, by tender lens, extends his view into the hidden region where cells wander and divide, and crystals form. He will, it is far more likely, be a good pantheist, if he cannot do like those who,

"When age, disease, and sorrow strike 'em,  
Incline to think there is a God or something very like him."

"No man is a hero to his *valet-de-chambre*," said Madame Cornuel. Perhaps because the observer has the soul of a *valet-de-chambre*. We likewise see the race in undress, but, I believe, think well of the race, probably better than the lawyer or even the minister. A sick-room does away with shams; for every weakness calls forth some strength; one poltroon may be the occasion of the appearance of heroes and heroines; one selfish imbecile opens in the family a mine of quiet strength. The moan of a sick child may call an ideal family into being. If we become rude and brusque outwardly, many sick-rooms put us on our best behavior. A child cannot be courted and won by haste or harshness.

I must not dwell longer on the good that may be wrought in us by virtue of our calling. We often do not know of these influences and often miss of them. It is more to my purpose to review the risks that we run; as it were, to put up Tyndall's viscid plates, and hastily, with a low power of the microscope, run over the field, and report the spores that doctors especially, from their calling, breathe in, that pervert our threefold nutrition, and warp us away from our growth to the full stature and symmetry of man.

What physical harm may we take? To be as systematic and unsatisfactory as a "system of medicine" with chapters assigned to different great specialists whose assembled monographs are like a great net with large meshes that let much slip through, I will say that the doctor starts like other men, with locomotor, circulatory, respiratory, digestive, and nervous systems. The first of these he usually supplements with a horse and buggy, through the use or abuse of which artificial aids his own inferior extremities usually atrophy, and frequently are fractured; his superior extremities are well exercised, and his torso is said by the irreverent laity to gradually telescope by long and constant jolting on the roads, the head sinking into the thorax, like a tortoise's, and the thorax into the pelvis, like a toy cup-and-ball. His circulation and respiration are more often helped than harmed by his mode of life if he has reasonable discretion. His digestion is apt to be his strong point in spite of irregular and often hasty meals. He reaches the land of *Eupnesia*, to be sure, by a different route from the one he directs his patients to follow. Cannot China, then, be reached as surely by traveling eastward, though most persons go thither *via* the overland route?

Brain and nerves must be in daily hard use, and well for the physician if they are only kept in perfect function by wise use in his calling, not worn and untuned. Loss of sleep, the strong tension of self-command required in dealing with the nervous invalid or the terrified family, worst of all the habit or worrying and the sudden misgiving with regard to his bolder measures that startles the doctor when the tide of brave confidence ebbs, as the sudden sight of a sharp, black ledge between the long waves appalls the sailor,—these must leave their marks somewhere on the hardiest.

Lastly, the diphtheritic membrane coughed into his very mouth, the malignant blood ferment, or the unsuspected, subtle taint from filth and crime entering by a mere scratch on his finger, the apparent duty to rise and face cold and fatigue when sick himself,—such things may fill out the catalogue of bodily ills that may come to our lot. Every lot has ills as bad. These happen to be ours.

Dr. Cotting, that keen censor of the ways of medical men, in two addresses delivered years apart before the Massachusetts Medical Society, threw strong light on the weak points in the intellectual armor of physicians through the centuries, namely, want of proper logic, jumping conclusions, believing and claiming that the patient's recovery was our cure, when we had never seen how disease, let alone, would behave. To remedy this failing he inculcates a healthy skepticism, and urges physicians to study the natural history of disease.

Another member of the State Society, Dr. Moore, lately reviewed in a careful and courageous paper, entitled, "Old School and New School Therapeutics," the medical field and finds that illogical methods and reasonings are the curse of medicine. He weighs in turn empirical and rational medicine and finds them wanting. Rational medicine is irrational, seldom curative, not even progressive; its theories, founded on sand, will neither secure the safety of the patient nor afford satisfaction to the physician. Empirical medicine has, he claims, accomplished absolutely nothing beyond the accidental discovery of a few clinical facts. These facts have not been set in order and made into a scheme. Our drugs do not deal with the whole disease, they are dangerous,

and we make a mistaken use of them. They only palliate. Since matters are so bad, what better course can he suggest, logical for the physician, curative to the patient? His remedy is this; study drug-action on the healthy and learn it *in its totality*. Study disease let alone, also in its totality, that is, as groups of symptoms, not even slighting the most trivial ones. Then "discover by induction the law that governs the relationship" which, he claims, undoubtedly exists between the two series of phenomena. This, he holds, has been found in homeopathy.

Both these writers, — I have chosen them as in a measure representing two opposite types of mind, — bring the same charge against the doctors, want of logic; but they suggest very different remedies: one would narrow our beliefs, yet hold fast to a few proven things; the other advises shifting ground and adopting a faith truly giving in advance a "substance" to "things hoped for" an "evidence" to "things not seen," and for curatives, so reputed, abandoning much invaluable palliative.

Yes, surely we are often illogical; but why? Because when we would be truly scientific the moral obligation starts up in the way. When the life of a man is trusted to us by his wife and family, few of us are nihilists in medicine enough to hold our hands and watch what Nature alone will do for him or to try an absolutely new course of treatment at a critical moment. It is not a sewing machine but a man with all his idiosyncrasies that is to be repaired; worse than that, we never served our apprenticeship in the workshop where he was made. We were led blindfold through that camp. But the sick man can't wait; we must do something and we must usually defer in part to the medical usage of the day, though if we are students of medical history, we have discouraging recollections while doing so of shifting medical fashions and even axioms.

See how the moral necessity interferes with the logical method of study. We believe in the *vis medicatrix Nature*, yet we remember a time when the *vis Nature* was all exerted in holding an intestinal obstruction in a spasmodic, relentless grasp, torturing the patient and seemingly threatening his life until our opium overcame this natural force, apparently to the signal comfort and saving of the patient; so we dare not wait and see whether Nature, in the end, would have tardily brought the man through by processes with such frightful stages in them. Often we can make out nothing like so clear a case as this of the opium for the use of our drug, or other interference, yet we take the step *because on the whole it recommends itself to us* for reasons that we should hate to be called on to exactly explain and defend before a critical board of censors. The case does wonderfully well, and it is a sore temptation, to us to sing the psalm beginning "*Post hoc ergo propter hoc*," in spite of the indignation that we feel when our sometime patients sing the same strain after taking sugar-of-milk pills labeled "*Apis*" or "*Aurum*," or after going to a clairvoyant. Yes, we certainly are in danger of too easy a belief.

Yet some of us, on the other hand, draw the other moral from such observations and say "We know that patients were bled and starved and recovered; were, a generation later, stimulated and overfed and recovered, and probably more yet would have lived out their days had they been let alone," and therefore will let a person burn in fever or lie awake coughing, saying, "If he dies, I, at least, shall not have it on my soul that I

hurt him by meddling interference." The pits of credulity and skepticism gape on each side, and the sight of those whose natural bias has made them tumble into one or other perplex the medical wayfarer, as the hobgoblins did Christian in the Pilgrim's Progress as he walked his narrow path.

Is not dogmatism as well as carelessness a mental tendency of the physician as well as of the clergyman, resulting from our encountering other minds that we feel must be borne down and convinced on a field and with weapons chosen by us? Do we not too often look at God's Universe as if it were little more than a hospital and forget that there may be — no, certainly are — more things in heaven and earth than our philosophy dreams of?

Last, what ugly traces may the days as they pass leave on the character of the doctor? As I think of them they may be classed under four heads.

That man, whatever his calling, who holds power unchecked in his hands is in danger. Power is a stimulant; it may be used to intoxication. We must often have implicit obedience, so come to insist on it where intelligent action would have been better for the patient. Sometimes we seem to take Fate into our hands, but there is peril in tampering with the ancient landmarks. Even the laity chafe sometimes that custom should forbid the shortening of lives which are a burden and a horror; oftener urge the prevention of life or a hasty choice of that apparently most desirable when one is endangered. The old metes and bounds are of more worth than they always seem. Do we always feel the weight of suffering that our word "incurable" or "hysterical" may bring with it? With us it is the opinion of a puzzled man; to the family the final verdict of profound science.

The second of these moral hurts is the loss of humane feeling. 'Tis the old stock accusation made against the profession, but I must think it far more apparent than real. Yet there is matter enough in the charge to make it well worth every man's thought. Few of us, I take it, get through our week's work without seeming at least rough, possibly brutal. The doctor looks at the sickness or operation humanely enough, but prosaically. To him it is an affair of every-day routine. The patient and his family see the same thing made great with all grizzly terrors of imagination. Yet this chimera is real to them, consequently when the doctor talks with them it seems as if the parties were at cross purposes, they speaking of the death of an only child, he of a cut finger. I don't pretend to tell you any new thing; we all know it when we consider the matter, but that usually comes, if at all, after leaving the house when the harm has been done, the feelings shocked.

When the frightened messenger rings our door-bell on a cold night he thinks life and death hangs on our speedy arrival. We don't believe it and take the rôle of counsel for the defendant. It looks savage to the family, however. In this capacity, too, of counsel for ourselves, we are apt to do a good deal of grumbling, which, after all is said, has n't helped matters, and has left a bad taste in our own mouths. We set forth planning to give the patient sulphate of zinc; we probably quiet down in the starlight and it may be no worse than sweet spirits of nitre. The chances really are that the years will strip off some of our armor and make us more vulnerable in our sympathies. It were a pity if it did not prove so.

To witness the great mystery, stand powerless and see a man

"Go through the strait and dreadful pass of death,  
Not ever to be questioned any more  
Save on the further side," —

is an experience that, however often undergone, brings with it a sense of awe; yet familiarity with the scene robs death of certain terrors. We see some compensations of suffering too; that Nature too has her æsthetics (excitement, use, fainting), and her children are not often called on to bear more than they can. We look at pains as warnings, as safeguards; see short sufferings cure long ills. There is a beast-like inhumanity: is there not too a god-like inhumanity that we should count one of our gains?

The doctor may often cry with Falstaff, "Lord, Lord, how this world is given to lying," when he hears himself quoted in detail as saying amazing things. Yet he is lucky if he can himself escape the charge. A man of quick wits can elude the point where a dull man must own or lie outright. So, O Public, be not hard in your judgments on a doctor of slow wits whose professional honor is pledged to keep secrets sacred from your most alert and pertinacious questionings. To be thus taught indifference to truth, — mere "formal verity," as the philosophers have it, — is a more real danger to us than a loss of humanity. We often have no right to tell the fact to the patient, the family, the public, yet must stand their examination. Plutarch says, in his essay on Inquisitiveness into Things Impertinent, "It was smartly answered by the Egyptian who, being asked what it was that he carried so closely, replied, it was therefore covered that it might be secret." Such an answer, however, seems seldom to give acute pleasure to the questioner.

The demon spreads a more subtle net when undue praise comes to us and our vanity is pleased by having things come out altogether too well. Every one of us I fear occasionally narrowly escapes playing the charlatan. Our brothers of the city may not consider the strain put on the courage and even the honesty of us, the rustic members of the guild, who are consulted, like oracles, on every branch and specialty of medical knowledge. Since the great growth of medical science in the last thirty years the learning that one man can attain must be spread very thin to cover the field. A doctor who attempts to be what the English sometimes call contemptuously a G. P. (not Grateful Patient, my hearers, but General Practitioner) may be likened to a general atlas, which, from the necessities of the case, must show in some sort the whole world, and so has to have large yellow spaces, like the old maps of Africa with perhaps some "Mountains of the Moon," or "Country of the Ethiopians," or even, as in the oldest maps, representations of monstrous beasts or anthropaghi to fill up with. Not every one is ready to write "Unexplored" on tracts which his friends seek to know about; sometimes, too, a hint of the dangerous beasts that may dwell there may seem expedient for the patient.

To us country doctors this temptation to hardness, to which our position educates us, in assuming and conducting all sorts of grave cases, becomes a source of danger inasmuch as we are only judged by an incompetent public opinion, not by good medical standards. We do what seems to us right and justifiable, but, as we are not intelligently criticised, we may become confident and confirmed in ways which are not sci-

tific or defensible, and still receive ignorant praise for it. Faust, in his reaction against his seemingly barren studies, sets forth this possibility with ghastly force, —

"Here was the medicine, — the patients died.  
None asked 'Who took it and remained alive?'  
Thus in these mountains, in these valleys wide,  
Our cure was than the plague a plague more fierce:  
To thousands have I given the poison: — they  
Have withered, they are dead and I survive  
To hear praise lavished on their murderer."

The doctor's honesty is often tried sorely by his desire, suggested by feelings of honor, kindness, and good taste, not to do or say anything injurious to a brother practitioner. If in his efforts to do this he stumbles over the boundary line of truth, usually he falls into one fault in trying to avoid another. The issue is often forced on him by ignorant persons who suppose that blame of the last doctor is incense to the new comer. But there is one point on which it has sometimes seemed to me that too little courage and frankness was shown; I mean the unnecessary assertion, evidently not felt, that the attending physician had done all that could be done; that he and the consultant were entirely agreed as to the nature of the case, and similar gratuitous overstatement. *Esprit de corps* is an excellent thing, but the interests of the patient are what the consultants are paid to consider, and truth is respectable. It is not necessary to emphasize disagreements or disparage the attending practitioner, but courtesy and truth are usually compatible where there is disagreement.

Besides our short-comings in humanity and entire honesty, we may sin against our self-respect. The Patriarch of the land of Uz is recorded to have sat patient and self-poised while the messengers of ill came fast upon each others heels with dire tidings of mischance. Few of us would serve a painter as a study for Job as we sit at the dinner table and the door-bell tolls the knell of our household comfort in troublesome summons to four different scenes of suffering, real or imagined. Our philosophy is shaken. We remember, as we review our conduct on the road that we probably did not appear to advantage to our families. When the physician's flank is turned by sickness at home, the calls of other sick people seem impertinent, and he takes and freely expresses the views of a pessimist.

Moral ills not of the first magnitude, but as it were, cutaneous disorders manifested by great irritability, from which few of us are quite free, are certain pettinesses of conduct, first of which I shall name sensitiveness when a patient leaves us for another adviser. To see the unloveliness of this weakness to advantage it is best to study it in another. Then one sees, until his own time of trial shall come, at least, that if one can't help feeling the mortification, the comeliest thing he can do is to put it absolutely out of sight. Surely, we do not own our patients, and if they seek other advice whom do we hurt by not bowing to them? Another evil of this class is worrying about the success of irregular or incompetent practitioners. This may in rare cases do some good and even be our duty, but usually it is safer to keep the contemplation of these absurdities to our private delectation and amusement.

One matter seems proper to mention here; I refer to the false position not infrequently taken by members of the Massachusetts Medical Society in letting themselves be called, without protest, and even calling themselves, "allopathic" physicians, and denouncing others

as quackish because they use certain drugs and doses, not because they take the name of an exclusive school. If our Fellows do this, how can we expect the laity to believe that our objection to homeopathy is more than class-jalousy.

A disease that only those of us escape whom the gods fashioned of a better clay is the losing sight of the metes and bounds of conventional propriety in conversation at home and abroad. This is only one phase of a wider mischief, the losing the man in the doctor, a matter well worth our heed. It is, I believe, customary among army officers to wear citizens' clothes when on leave of absence. It is a symbol which should be a lesson to all professions. The public shares the blame with us if we don't do this, for they will consider us as doctors wherever we may go when off duty. First, man; second, citizen; and then doctor, is the right order. The man is a loser and to be pitied who is merely "doctor" in the eyes of his own wife and children. The town will be better if he feels the responsibility of a citizen that he owes to it. More than that, wider interests and broader views will make him no worse physician. There is something very dismal, though touching and also heroic, in the old age of some brave practitioners who have given themselves so without reserve to their profession that they have no other resource, cannot stop until death give them their release from a work of which they have ceased to feel anything but the hard duties and fatigues which yet have become an iron fate to them.

Yet this is better than that view of our professional life which regards it merely as a livelihood, a view one often hears maintained. Certainly that is a legitimate and healthy consideration; a leading one, if you will, with most of us, but we cannot stop there. The opportunities, the privileges inseparable from our work assert its dignity, and at once claim the attention of every worthy member. Yet we are too prone to forget the higher perquisites of our calling. The poor, from the very conditions of their lives, as we all know, are the persons most liable to accident and disease, which cuts off their earnings when most needed. Yet we sometimes hear physicians speaking as if a personal outrage had been done them when these facts are taken into consideration and a bill abated or excused. Perhaps we should be more grateful than we are that, while others in hard times begin retrenchment in their charity account, we have the privilege of exercising a compulsory charity all the time, and then especially.

"However hard the hardest diagnosis of disease may be," said Traube, of Berlin, to his pupils in the Clinique, "the question what to do about it is yet a harder one." Yet by the terms of our enlistment we are daily called on to assume this office, and since you have placed me here to-day, and I have gone thus far in stating some of the influences that work for our harm, I must not stop here, but do my endeavor to show how we may best oppose them. First, then, how shall we meet the physical ills which are beyond mere exposure, nervous wear and tear, in the strong English of the Bible, "virtue going out from us"?

The first great remedy is, in most cases at least, given with the need for it. That which the doctor may prescribe as an expensive hygienic luxury to his patient is to him, like his pocket-case, a professional necessity, namely, a horse. The prophet said to the faithful, "Blessings, success, and rich gain shall be hung to the forelock of the horse till the day of resur-

rection."<sup>1</sup> Edward, Lord Herbert of Cherbury, said "A good rider on a good horse is as much above himself and others as the world can make him." Ride your horse sometimes, even at the risk of causing a universal hilarity to pervade the village street. It is easier to carry fluid extracts in a holster than it was for the fathers to carry bark and leaves by the pound in their saddle-bags. A small portmanteau behind the saddle will hold forceps and specula. You can go by new and adventurous paths through woods and on turf, instead of being, like a locomotive, a slave to the graded road. When you know how riding will be easier for the horse and warmer for you than the open buggy, or the sleigh if the snow be deep. If you drive, by no means have a sulky, and, when you can, carry a friend (not a sick one) who is a cheerful talker and good sitter, is well wrapped up, and armed with book or sketching-block. When you emerge from the house of the hysterical patient, and let off the tension of steady and kind professional behavior, and feel with Cullen that "stripes may be occasionally of service in the treatment of the insane," then to have some one with whom you may talk in the sunshine of books, or art, or trees, may save you from suicide. Sometimes leave the highway for the by-ways and go on foot on good days when there is time. The adventurous old doctor is still talked of in this neighborhood who drove on the ice, now on the meadow, now on the river, to the remote farm until he and his horse ran a race with the thaw. His neighbors said that his horses ran away with him; he had never found it out, nor had one that would run faster than he was willing to travel. Once only in a half century he failed to see his patients on account of weather, a day on which his sleigh overset twice in the drifts in the first few rods. He unharnessed, mounted the horse, and set him at the drifts, but slipped over his crump as he plunged in them. Only then did he feel justified in giving up for the day.

We who live beyond the suburb have on our rounds opportunity that the merchant or lawyer may well envy us, to learn to know, which means to learn to love, Nature. From willow-catkins and alder-tassels we may read, if our eyes are trained, through all the sure almanac of May flower, rhodora, pink azalea, arbutus, red lilies, purple grass, rhexia, fringed gentian, to witch hazel and black-alder berries before white crystals and gleams of ice jewels must take their places. An easier study, in a book printed large on purpose that he who rides fastest may read, is, the forest trees and shrubs. You may learn them by their leaves in summer and in winter their barks will be a nicer test of your observation.

One of our Fellows, eminent both as physician and professor, confessed to the practice of trying whether he could hit refuse tomato cans and bits of coal with his wheel as he drove through the suburbs, — a needed relaxation of the faculties, but happy are they who are out of the zone of perpetual tomato can, and have a lovelier equivalent for mental refreshment furnished them by the pine woods or meadows. To cultivate the love of Nature either from a scientific or artistic point of view is a safeguard to nerves, and heals our tempers between patients. It is, after all, a privilege, if we will so regard it, to know what it is like out of

<sup>1</sup> "Les bénédictions, les bons succès, et un riche butin seront attachés au fouet des chevaux jusqu'au jour de la Résurrection," Mahomet, quoted by Abd-el-Kader in "Les Chevaux du Sahara," by Gen. E. A. Dumas.

doors any hour of every day and night in the year; to know

"Clouds and great stars, thunders and snows,  
The blue, sad fields and folds of air."

I have known thus to be acquired a taste for weather as such.—certainly a valuable gift of mind in New England.

It has been shown that the intellectual methods of physicians are open to criticism and I have earlier presented the two extreme views that different classes of mind may reach through contemplating the gaps in medical knowledge so far unfilled. The man who can hold a middle course will not only take more pleasure in his profession, but will help his patients more, a matter of some importance. Is this an unreasonable position? Because we cannot walk shall we refuse to creep? We have not an exact science like mathematics, but there is all the more room for growth, for genius. The fact is that we must not be so illogical as to try to be strictly logical until more data are found. Till then we will admit that we grope, but not without gleams of light on our way, that we believe grow brighter as we advance. Whence come those gleams? Partly from chance bits of touch-wood found by the way. Chiefly from the work-rooms of physiological investigators, to whom our debt is greater than the fox-hunting gentry who are shocked at their work realize. These last would be loth to give up the important knowledge these men have honestly found should tetanus, heart-failure, many forms of poisoning, occur in their own families, and it seems as if another score of years would give astonishing results from the patient investigation of this class into tuberculosis, diphtheria, typhoid, and other blood poisons, the promising field that inoculation seems to open.

Because the rational method has not enabled us to completely meet and vanquish with a drug each disease, shall we therefore despise it, and look round for a complete system and creed to rest, perhaps to slumber, in? Shall the practice of medicine be merely drug practice, and for specifics yet unfound shall we abandon our "mere palliatives," opium, ether, quinine, digitalis, jaborandi, alcohol, the antiseptics? Because the first theories based on studies and experiments in chemistry, physiology, pathology, sciences almost of yesterday, proved crude and not subtle enough, shall we despise the daily waxing light that these are shedding on our work? I am sure I speak for many when I say that each day gives us reason to bless the fathers who proved these "mere alleviations," to feel proud of those, our brothers, who, with sight sharpened and extended by science, push further into the darkness searching for the causes which our associate, above quoted, despairs of their ever finding. It needs but a moment's thought of the advance in medical science, and medical science *directly contributing to the successful treatment of disease*, to convince us that our chosen profession is no pool of stagnation, no hopeless Babel of contradictory voices, but a calling in which we can find more satisfaction in *curing*, which, rightly read, means *caring* for our patients, comforting their pain, enriching their blood, allaying the consuming fire in their tissues, strengthening their weak wills, freeing them from self-forged chains, widening their range of ideas, building up their hope, than in telling them what is good for sore throat or cures Bright's disease, and if this is the true way and ours the false, then I, for one, say with Cicero, "Rather, by Hercules, would I be in

the wrong in such company than in the right with those men."

But look back, says one, your science and the practice following it has, through the ages, swung hither and thither, now to daring interference, now to cautious expectancy; it shifts like a very weather-cock. Rather, we hope, like the compass needle when the box is shaken; it oscillates, now east, now west, but with shorter excursions each time, and, though medical knowledge may never, like that, rest at last pointing for us one way with absolute certainty, yet each time careful minds in healthy action and reaction go over the same ground, new facts will be found, the checks and limitations more carefully considered and recorded to guide those who come later.

"Nay, never falter: no great deed is done  
By falterers who ask for certainty.  
No good is certain but the steadfast mind,  
The undivided will to seek the good.  
'Tis that compels the elements and wrings  
A human music from the indifferent air."

Let us honestly and humbly admit that we know little so far, but enough to make our calling worthy in our eyes. But rightly to use what we have we must take high ground go to the watch-tower, and sweep the horizon, not look through the office window alone. To see vital phenomena with too much of a drug-dealer's eye is one of our faults. Perhaps Marley's ghost was, as Scrooge thought, merely a bit of undigested potato, but we must look deeper would we explain all spiritual experiences. The final causes may be physiological, but to find them we must look to more than the condition of the *prima vie*.

A man's calling, if it be the right one, should confirm his strength and stimulate his growth. What forces shall we call to our side when we fear lest the rushing tides of our busy life wear and sap our moral foundations? To be responsible for his power merely to the community, since they are ignorant of the conditions, will not even satisfy the physician. He must be responsible to himself and to his honored brotherhood down through all the ages.

Should we detect any loss of humanity in ourselves, even in moments, consider that we hold of all others the humane profession; it should be that by the terms of its existence. We can afford no loss there. If the helper is hard and inconsiderate whence shall the help come? Patient then and steady he must be and cultivate the imagination that he may apply the old and safe test, putting himself in the patient's place. Yes, but with a difference too, for by so doing he must endow the sick man with confidence not his own hitherto, and remember but enough of his misgivings to make necessary allowance for weakness, unaltered in his cruelly beneficent purpose as a Fate. He must be well in command of himself to exactly dispense the two grains of sternness to eight of sunshine unalloyed that the case may require. To have gone through in his own person the sickness he treats or the operation he is to perform is a fortunate accident as it may give a tenderness in handling that no other learning can and also sometimes convince him that, were the terrors stripped away from the patient's mind, the real cutting would not be worth a thought.

In smaller matters, if we almost from necessity encase ourselves in a rough coat, this fact in natural history is worth remembering, namely, that, though the porcupine is now acquitted by science of willfully shooting his quills at all who come near him, it is

equally certain that if you touch him they will come off, quite unconsciously on his part, perhaps, but with a fatal facility to pierce the skin they come in contact with. Some material a little rougher than porcupine skin should be chosen for the physician's great coat. "When thou givest a gift, use not uncomfortable words."

The disgust felt at the various petty lies or misrepresentations that he is sure to hear about himself is a healthy influence to the doctor on the side of truth in word and act. Certainly, if it teaches him nothing else, it should teach him with regard to brother physicians the wisdom of the reminder of Ecclesiastics, "Many times it is a slander and believe not every tale." Sometimes it seems our plainest duty to the patient to withhold the truth, at least for a time. To be non-committal or more may be wise and legitimate, but on the other hand, a habit of mystery may be formed which is dangerous to the physician and makes him much less trusted and depended on than should be his right. It must also be remembered that the tendency to mystery is the time-honored badge of quackery. The "wizards that peep and mutter" cannot, with intelligent patients, stand comparison with the blunt and honest doctor. He holds the strong and dignified position. Fear of being deposed from the throne of infallibility is a strong temptation to petty and unworthy deceit that often overleaps itself. Often it happens that the frank and simple admission of his limitations goes farther to win confidence than any other course could; yes, gives the doubtful case into his hands.

When we come in consultation, or a question arises of a change of medical attendant we can't say too often to ourselves, "remember that the interests of the patient rank before every other consideration."

Speech, kindly, strong, persuasive, is a chief article in the materia medica and must be used often in very large doses, but the saving discretion where to stop, when to keep silence and how to guard our right to silence is a great gift, hard to come by.

Failures in humanity or honesty must bring in their train loss of self-respect, but this expression in a narrower sense was the fittest I could find to include some of the remaining adverse moral influences that we feel. The only way to steel ourselves against the expression, if not entirely against the feeling, of annoyance at the sure interruption which comes when we fondly make plans for private comfort and amusement, is the daily consideration of the subject in advance and remembering that sudden interruption of a trying and painful character, the disappointment of our hopes, the failure of our measures, even the desertions of our patients, are among the conditions that we accepted at our enlistment and that, if we would not have our conduct daily unbecoming, we must never allow ourselves to be surprised into impatience:—

"He through the heat of conflict keeps the law  
In calmness made and sees what he foresaw."

To do this we must take large views, stand apart, like the artist, and follow his rule,—look three times at the figure of the ideal physician to once at our poor copy of him. Seize every opportunity that we can to talk with living masters in other walks of life; sometimes when we meet colleagues let shop-talk go and discuss the humanities. More than all, busy though we be, don't spare to medicine all our reading time. Read about the heroes,—our craft has been rich in them,

"We find in our dull road their shining track"

and forget that we are foot-sore.

How can we teach the breaking-down business man or care-worn housewife the folly of his or her course, wearily getting ready to live until all the years of life are gone, if we don't live ourselves as we go, be men as well as doctors? Keep your personal identity, first of all, in the family. Don't be doctor and not husband and father. Insist on your social rights and refuse to be doctor at tea-parties or dances. Claim your right to a vacation and drop medicine like a hot iron. Your patients may grudge it you, but will reap their gain in it.

Prometheus, forethought, in the myth, was the helper, the hero, before whom Zeus, his tormentor, trembled. Epimetheus, afterthought, was a craven and brought no help to man. When the case where we were not prospered and all our thought and work went for nothing and the tragedy that we fought so hard against came steadily on to its fulfillment, rises before our minds,—look at it, give it just so much thought as it should have to see if there is any new light to use again in time of need, but not one thought more. Even in that extreme case where we question whether our well meant act did not help on, instead of staying, the disaster, ask would you not rather know at the end of a long practice that three persons had died through your active treatment, than feel that you had let forty die through your fear of taking the heavy responsibility on your soul. It was a wise counsel that the prophetess Brynhild, in the Norse epic, gave the hero Sigurli,

"Be wise and cherish thine hope in the freshness of the days  
And scatter the seed of thine hand in the field of the people's  
praise,  
And fair shall it fall in the furrow, and some the earth shall speed,  
And the sons of men shall marvel at the blossom of the deed;  
And some the earth shall speed not; nay, rather the wind of  
Heaven  
Shall waft it away from thy longing, and a gift to the Gods hast  
thou given,  
And a tree for the roof and the wall in the house of the hope that  
shall be,  
Though it seemeth our very sorrow and the grief of thee and me.

Wilt thou do the deed and repent it? Thou hadst better never  
been born.

Wilt thou do the deed and exalt it? Then thy fame shall be out-  
worn.

Thou shalt do the deed and abide it and sit on thy throne on high  
And look on to-day and to-morrow as those that never die."

Last, consider the privileges of our high calling. We are spared dealing with crime. A fairer side of humanity, through suffering, is shown to us. We are honored with trust, the fullest that our kind can give. The priest and the man of law may be held at arm's length, but sooner or later the doctor crosses every threshold. He may find beggars in lofty chambers and the saints and princes in the hovels and becomes catholic in his ideas, but I think he would not always think it a gain to place them otherwise. He may eat, like Cæsar, the anointed asparagus and praise the hospitality so unavorily expressed. He has eaten of the tree of knowledge of good and evil, but he does not fear the anger of the God.

In the old legends of our race it is recorded that when hero or demigod pitied man's lot and gave him help, whether fire, or letters, or arts, the Gods never forgave it and brought vengeance on the benefactor,—the gifts they could not take back. If then we suffer, that too is one of the privileges of our class, as many have found.

We have enough then to inspire us in our work.

Can we make it worthy? To admit the doubt is the first step toward failure. The motive is all, whether the soldier falls in the first parallel or enters the square of the city in triumph. Let the outward forces and even the outer inside forces of our dual nature do what they can or must against us, but let the inner force, your proper force, be exerted and it will tell too in the resultant, for that force, whatever, whence-ever it be, even the stern materialist must admit, is as valid, as irresistible, to the extent of its co-efficient, as the lightning spark or planetary motion or primal sunlight with which it is convertible.

### CASES OF POISONING FROM DRINKING IMPURE WATER.<sup>1</sup>

BY JAMES H. HUTCHINSON, M. D.,

\* *One of the Attending Physicians to the Pennsylvania Hospital.*

DURING the past three months I have had under my care at the Pennsylvania Hospital a series of cases, which presented a rather unusual set of symptoms, and which possesses so much interest that I feel justified in taking up your time this evening with a brief account of them.

The patients were all Germans, and were all employed in a large sugar refinery in this city at the foot of Bainbridge Street — on the Delaware River front; where, however, none of them had worked more than two, or at most three, weeks before the occurrence of the attack. The cases so closely resemble one another, that the history of one will suffice for my purpose. I have selected that of the first patient admitted, which was, moreover, much the severest of them all.

CASE I. R. R., aged twenty-one, born in Germany, single, shoemaker, was admitted into the men's medical ward of the Pennsylvania Hospital on January 30, 1882. One of his sisters is said to have died of consumption, but with this exception his family history is good. His own health has always been good until two weeks ago, when, without any apparent cause, he was seized with diarrhoea, attended with a good deal of prostration. He has had as many as ten to fourteen stools a day, and has also had at times nausea and vomiting, but is sure that he never has had fever. Yesterday the diarrhoea ceased, and he has had no passage since. Upon admission the patient is anæmic, and complains of excessive weakness, of vertigo, and of pains in his back and limbs. The tongue is dryish, and coated with a thin whitish fur; the appetite poor, and the pulse slow; the temperature subnormal, 97°; there is no tympany. The examination of the heart, lungs, and urine gives negative results only; he was ordered a pill containing nitrate of silver one third of a grain, and opium one fourth of a grain, three times daily, and placed upon a restricted diet.

February 2d. The patient's bowels have not been moved since his admission; he feels less weak than when admitted; his tongue is also less coated, but his temperature is still subnormal. The use of the pill was discontinued, and he was ordered a teaspoonful of Huxham's tincture three times daily.

February 20th. The bowels are now moved regu-

larly; he does not appear to gain strength; he was, therefore, ordered cod-liver oil.

March 6th. Discharged cured.

I confess that when this case first came under my care, I was puzzled how to explain the symptoms it presented. The presence of excessive prostration with a history of diarrhoea lasting for two weeks, seemed to point to typhoid fever as their most probable cause. Against this hypothesis was the fact that the patient was positive in his assertions that he had not had fever at any time since he was taken sick, that none was present at the time of his admission or subsequently, and that there was no tympany or rose colored spots. His condition called, however, for a supporting treatment, and I thought it best to restrict his diet to liquid articles of food.

The other cases came in rapid succession, and presented the same symptoms as the first case. There were in all of them prostration, slow, compressible and often dicrotic pulse, subnormal temperature, diarrhoea, sometimes accompanied by slight pain in the bowels, and absence of tympany. This similarity of symptoms appeared to indicate an identity of cause, and it was soon discovered that in addition to having been employed in the same refinery, they had been all subjected to an influence which seems to me sufficient to explain the symptoms from which they suffered. It was found upon inquiry that water from the river Delaware is introduced into the refinery for use in cleansing the evaporating pans, and that, after being used for this purpose, is returned to the river above the point although at a considerable distance from that at which it is taken.<sup>2</sup> The water is distributed throughout the building, and being more accessible to the workmen than the ordinary hydrant water is freely used by them for drinking purposes. The water, although said to be filtered before being put to the use first referred to, is probably from the presence of organic impurities unfit to drink.

There can be but little doubt that the use of the water of the Delaware River, contaminated as it must be opposite Bainbridge Street by sewage, was the cause of the singular symptoms observed in the six patients who came under my care. Impure as it was, it did not, however, produce typhoid fever, and my cases show that while impure water may produce prostration as great as that seen in this disease, it will not produce the fever itself, unless it contains the specific typhoid germs.

The symptoms presented by these cases seem to have indicated the existence of blood poisoning rather than of irritation of the bowels. The latter could hardly have existed without the presence of a certain amount of fever. The temperature records will show that at no time in any one of the cases was there any elevation of temperature above the normal. The stools, too, indicated the existence of relaxation rather than of inflammation: they were rather dark in color and watery, and never presented the ochrey yellow appearance of the stools of typhoid fever. The cases further show that persons may become accustomed to the use of an impure water, or that at all events it may cease to excite in them after a certain time any active symptoms. It will be remembered that all the patients had only recently been employed in the fac-

<sup>2</sup> The water is taken from the foot of a long wharf projecting into the river; it is returned at the point nearest the factory. These two points are distant from each other about one hundred and fifty feet.

<sup>1</sup> Read before the College of Physicians, Philadelphia.

tory, and the effects of drinking the water had shown themselves very soon after they had entered upon their duties. The older hands drank the water with impunity.

The cases all did well, and required little treatment. Hope's camphor mixture being used in most of the cases to check the diarrhoea, and quinia or Huxham's tincture as a tonic.

It may be well to add that the attention of the proprietors of the refinery has been called to the supposed cause of the illness of their workmen, and they have taken the proper precaution to prevent the occurrence of further sickness among them by cautioning them against the use of this water for drinking purposes.

I have appended to this paper the histories of the remaining five cases, which I had the opportunity of observing. They are drawn up from notes taken by Dr. J. M. Fox.

CASE II. Diarrhoea with typhoid prostration. A. W., aged eighteen; born in Germany, single, baker; admitted March 1, 1882; discharged March 13, 1882, cured. He came to this country last September; has always been very healthy until two weeks ago, when he began feeling weak and miserable, and to have headaches and diarrhoea, which have continued.

Upon admission has no fever; temperature subnormal; appetite poor; tongue slightly coated; some hebetude and slight headache; no fullness of abdomen; a few râles heard over apex of right lung; examination of heart and urine negative. Ordered quinine grains viij and liquid diet.

March 2d. Tongue clean; only one passage from bowels; pulse slow, with a tendency to reduplication.

March 3d. Bowels not moved since; no fever; feels much better, but is still rather dull.

March 13th. Continued to improve, and is now well.

CASE III. Diarrhoea with typhoid prostration. H. S., aged twenty-eight; born in Germany, single, laborer; admitted March 13, 1882; discharged March 20, 1882, cured. Has generally been very healthy; eight days ago he began to have diarrhoea, pain in the stomach and limbs, headache, and vomiting, and these symptoms have continued; has had as many as twelve loose stools a day.

He has been working in a sugar refinery, and is the third patient who has been admitted from there into the hospital within the last month and a half, with much the same symptoms, except that the prostration of the other two (R. R. and A. W.) was more marked. He says that he has been in the habit of drinking the water that is pumped from the Delaware, which is very likely the cause of the trouble.

Upon admission patient feels weak and dull, has headache, vomiting, and diarrhoea; pulse weak and reduplicated (this was also the case with the other two patients); appetite good; tongue clean. Examination of heart, lungs, and urine gives negative results. Hope's camphor mixt. f ʒss. was administered as needed.

March 15th. Bowels are still loose, and passages are light colored; no more vomiting; diet has been restricted; camphor mixt. was stopped, and powdered opium one quarter of a grain, with oxide of silver one third of a grain were given three times daily.

March 19th. Diarrhoea has been checked, and he now feels and looks quite well. His temperature since admission has ranged from 98° F. to 98.5° F.

CASE IV. Diarrhoea with typhoid prostration. F.

S., aged thirty-four, born in Germany, laborer; admitted April 17, 1882; discharged April 25, 1882, cured. Has generally been very healthy. Two weeks ago, while working at a sugar refinery, he was taken with pain in the bowels and diarrhoea, which have continued up to the present time.

Upon admission patient was somewhat prostrated; has diarrhoea and tenderness in the epigastric region; the tongue is slightly coated in centre, moist; appetite poor; pulse slow; no fever. Heart, lungs, and urine normal. Ordered quinine gr. viij. daily. Hope's camph. mixt. f ʒss. as needed, and liquid diet.

April 20th. Diarrhoea has been checked, and he feels much better.

April 25th. Feels very well; bowels regular; appetite good. Temperature has ranged from 98° F. to 98.5° F.

CASE V. Diarrhoea with typhoid prostration. M. Z., aged twenty-nine, born in Germany, laborer; admitted April 17, 1882; discharged April 25, 1882, cured. Eight days ago, while working at a sugar refinery, he began having diarrhoea and pain in the bowels, and these have continued up to the present time.

Upon admission his face is slightly flushed, and he has a typhoid appearance; is somewhat prostrated; tongue coated in centre, moist; pulse slow; bowels were opened six times during the night. He has no fever, and there is no fullness of the abdomen. Examination of heart, lungs, and urine gives negative results. Ordered Hope's camphor mixt. f ʒss. to be given as needed, quinine gr. viij. daily, and liquid diet.

April 23d. Feels very well; bowels regular; no pain; appetite is good. Temperature has ranged from 98° F. to 98.5° F.

CASE VI. Diarrhoea with typhoid prostration. M. W., aged nineteen, born in Germany, single, laborer; admitted April 24, 1882; discharged April 29, 1882, cured. Has generally been very healthy. Came to this country eight months ago; two weeks ago he began working at a sugar refinery; about a week ago he was taken with diarrhoea, which has since become worse; has not had any nausea or pain.

Upon admission patient is slightly prostrated; face flushed; temperature also subnormal, 98° F.; tongue slightly furred, moist; pulse slow; appetite poor; bowels loose. Examination of heart, lungs, and urine gives negative results. Ordered Hope's camphor mixt. f ʒss. to be given as needed.

April 29th. Diarrhoea has been checked, appetite has improved, and he seems very well again.

## RECENT PROGRESS IN OTOTOLOGY.

BY J. ORNE GREEN, M. D.

IN the *Archiv für Ohrenheilkunde*<sup>1</sup> Schwartzke is publishing his second series of fifty cases of perforation of the mastoid process, the complete history of each being given, and the whole article forming a most instructive description of a very large variety of diseases of that part. The series is not yet complete, but the following cases are particularly of interest from the points of diagnosis, pathology, and treatment. The first two cases are specially interesting from the fact that the mastoid was so extensively diseased, and yet there were no external manifestations of the con-

<sup>1</sup> Vols. xvi., xvii., and xviii.

dition, although in one the external table had even been perforated. In the third case the tympanic disease was catarrhal, while the mastoid disease was distinctly purulent. In the fourth case the natural opening of the mastoid inflammation instead of taking place externally was into the meatus.

**CHRONIC SUPPURATION OF THE MIDDLE EAR; FISTULA THROUGH THE BONE OF THE MASTOID WITHOUT ANY EXTERNAL MANIFESTATIONS; PERFORATION OF THE MASTOID WITH THE GOUGE; CURE.**

A boy aged five years had chronic suppuration of both tympana, complicated with adenoid hypertrophies of the naso-pharynx. The right meatus was filled with granulations, and the drum-membrane was largely destroyed; the left tympanum was filled with mucopurulent exudation and the membrana tympani had a fine perforation.

The granulations of the right ear and adenoid hypertrophies in the naso-pharynx were removed, and the otorrhea on that side treated for some five months without improvement. During that time there was never any pain upon pressure, or any swelling in the mastoid region, but as the odor of the pus was very offensive in spite of the most careful cleansing and disinfection, and as there was frequent pain in the ear and head, with occasional attacks of fever and progressive emaciation, a retention of pus was diagnosed, and Schwartz decided to open the mastoid. The periosteum, which was perfectly normal, having been incised and pushed aside, a fine fistulous opening was found in the bone running into the mastoid antrum, which was enlarged with the gouge and hammer, and that cavity freely opened, the walls scraped with the sharp spoon, and a drainage tube inserted. Immediately after the operation irrigation showed a communication with the pharynx, but none was established with the meatus till the douching had been used for six days. Communication with the meatus varied very much, probably from the obstruction of granulations, but when free, caseous pus was washed out in considerable quantities. The only treatment used was irrigation and drainage, and at the end of twenty-one months the otorrhea had ceased, the membrana tympani had healed by cicatricial tissue, the fistula had closed, and the hearing, previously nearly wanting, had improved so that a whisper could be heard several yards away.

**CHRONIC SUPPURATION OF THE MIDDLE EAR; CENTRAL CARIES OF THE MASTOID WITHOUT EXTERNAL MANIFESTATIONS OF ANY KIND; PERFORATION OF THE MASTOID; CURE.**

A boy aged eleven years, of bad constitution, with a decided predisposition to tuberculosis, had had chronic suppuration of both tympana for ten years, with the loss of large portions of both drum-membranes. The otorrhea on the left side was cured by caustic solutions of argentic nitrate, but that on the right resisted all treatment, although faithfully followed for eighteen months. The penetrating odor of the pus remained in spite of all disinfection, and the pus was felt to be filled with osseous sand. During the treatment osteophytes had developed on the posterior wall of the meatus, and it was finally decided to perforate the mastoid, although there had never been any tenderness or swelling. The unusually thick corticalis was opened with gouge and hammer, and the walls of the mastoid cavity, which were covered with offensive pus, were

thoroughly scraped with the sharp spoon, a drainage tube inserted, and twice daily the bone was carefully washed out, the fluid passing out freely through the meatus and nose. At the end of two months the offensive odor had entirely disappeared, and in another month all discharge had ceased.

The fistula was kept open for some eight months, the drainage tube having been replaced by the peculiar leaden tube which is almost always used by Schwartz, but there was no return of inflammation, and the removal of the lead was followed by rapid healing of the wound. One of the most important features in the cases, which shows the ill effects upon the general health of these ear-diseases, was the very great improvement in the health following the cure of the ear-disease. The boy, previously pale and sickly and with a constant cough, became in a few months very robust.

**ACUTE ABSCESS IN THE MASTOID CELLS WITHOUT PERFORATION OF THE DRUM-MEMBRANE; PERFORATION OF THE MASTOID WITH THE CHISEL; CURE.**

A man aged forty-one years was seized with a chill, followed by pain behind the right ear, and soon by some swelling over the mastoid, but without discharge from the ear. Seen after the symptoms had continued for fourteen days the tympanum was found inflamed, and paracentesis evacuated jelly-like mucus; the swelling of the mastoid had gone, but some tenderness remained. The tympanum was readily kept clear, the tenderness of the mastoid diminished, but swelling of its integument increased, and after some weeks, as the fever continued and there was total loss of appetite, it was decided to perforate the mastoid cells. The bone was solid and healthy, except a small spot in the upper part which was discolored, and being opened with a chisel proved to be very porous. On opening the cells thick yellow pus was evacuated. A drainage tube was inserted, daily irrigation used, and the discharge soon ceased, the paracentesis-opening in the drum-membrane healed, and the hearing became normal.

**CENTRAL CARIES OF THE MASTOID, WITH FISTULA INTO THE MEATUS; PERFORATION OF THE MASTOID; CURE.**

A boy nine years old had suffered for over eight years with a fetid otorrhea on the right side, frequent pain, and occasional swelling behind the ear. Examination showed a hard cellular infiltration at the point of the mastoid, with a fistula through the posterior osseous wall of the meatus, which was surrounded by granulations and into which a bent probe passed freely.

At the operation the corticalis was healthy and solid, but the whole cavity of the mastoid was carious, and was scraped thoroughly with a sharp spoon. The lead tube was inserted and daily irrigation used, with the result of a cessation of the otorrhea in the course of a few months, and complete recovery from all inflammation and great improvement in the hearing.

**POISONING FROM THE INSTILLATION OF ATROPINE INTO THE HEALTHY AUDITORY MEATUS.**

Knapp<sup>1</sup> reports a case of transient poisoning from two instillations of a few drops each of a one-half per cent. solution of sulphate of atropia into a healthy meatus for the relief of pain. The solution was used once in the evening and again the next morning. Four and a half

<sup>1</sup> Archives of Otolaryngology, March, 1882.

hours after the last application the hands and fingers began to swell and become stiff, the eyes became swollen, and the face scarlet, the throat dry, tongue thick, lower lip swollen and hanging down, violent palpitation, and feeling of intense heat, which could not be relieved by cold water. These symptoms increased steadily for four and a half hours; they then began to abate, and in one hour had entirely disappeared. The family physician reported that the patient, a lady, had previously shown an unusual susceptibility to atropine.

## Reports of Societies.

### MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

#### THE SURGICAL TREATMENT OF NASAL CATARRH.

At a stated meeting of the Society held May 22d, Dr. WILLIAM C. JARVIS read a paper entitled *The Surgical Treatment of Nasal Catarrh, with Practical Demonstration*. After a few introductory remarks, Dr. Jarvis said that he recognized five tissue formations in chronic nasal catarrh which were as follows: (1) Hypertrophy of the tissues overlying the turbinated bones; (2) thickening of tissues over the septum; (3) deviation of the septum; (4) adenoma of the vault of the pharynx, and (5) gelatinous polypi.

Congestive hypertrophy, he said, was, as a rule, readily recognized; but in many cases of so-called hypertrophy the condition present was due to a loss of retractile power (a species of paresis) rather than to true hypertrophy. The tissues over the lower turbinated bone were more liable to become hypertrophied than those over the others on account of their inferior position, and the hypertrophy was more apt to be posterior than anterior. He made a distinction between anterior and posterior hypertrophy, on account of the difference in the surgical treatment called for in each. *Second*. Thickening of the tissues over the septum. By the classification adopted a large number of cases of so-called deviated septum were at once done away with. There was a certain amount of turbinated hypertrophy always found in this second class of cases; and thickening over the vomer was also not infrequently met with.

Deviation of the nasal septum might, of course, be either osseous or cartilaginous. This was an exceedingly common cause of catarrh, and was therefore a condition of great practical importance. The trouble frequently dated from a blow, and as it usually occurred in those who were otherwise in good health, the happiest results were apt to follow the removal of the source of difficulty. Deviation of the cartilaginous septum was of two varieties, localized and general. The first variety did not always set up catarrh, as the seat of deviation might be entirely without the nares; but in that case it was generally desirable to operate on account of the more or less marked deformity present. The general variety was apt to be of a sigmoid character.

Gelatinous polypi formerly were considered as independent growths, and they often bore a peculiar resemblance to the mucous membrane seen in hypertrophic nasal catarrh. To adenoma of the vault of the pharynx he would assign only a place of secondary importance. The different conditions of which he had

been speaking were illustrated by large colored drawings copied from actual cases.

Dr. Jarvis next described and exhibited the various instruments and appliances which he was in the habit of employing in his various operations. The first of these was the *éraseur* which he introduced some time ago to the notice of the profession, one of the prominent characteristics of which was the finely tempered steel piano wire used in connection with it. The next was a combined mirror and tongue-depressor, the advantage of which was that it could be held with one hand while the other was operating with the *éraseur*. The other apparatus mentioned consisted of some convenient tape-holders, two varieties of septum scissors, and a set of transfixion needles, which varied in size, and in general resembled ordinary glover's needles, except that they were curved at different angles.

He then went on to describe his methods of treatment in more or less detail. For posterior hypertrophies he was in the habit of using the *éraseur*, as there was always somewhat of a constriction at the point where the mass of tissue protruded beyond the nares, about which the wire loop could be readily retained. The laryngoscopic mirror might or might not be used according to circumstances; but there were many cases in which the wire could be satisfactorily adjusted without such assistance. Smooth and firm sessile hypertrophies were not amenable to this method of treatment; but if they were soft, notwithstanding their sessile character, the operation was generally successful. In firm non-pedunculated hypertrophies he was accustomed to insert his transfixion needles before applying the *éraseur*; and if the hypertrophy were posterior there was great danger of hemorrhage, so that it was necessary to proceed with caution. The localized hypertrophies over the vomer were sometimes quite difficult to remove.

Thickening of the tissues over the septum (which had the effect of distorting the nasal gutter) constituted one of the most frequent causes of chronic nasal catarrh. In such conditions all treatment by means of washes and sprays afforded only temporary relief, and failed of a permanent cure as long as any deviation remained. In such cases he employed a transfixion needle with a very marked curve with the *éraseur*, and by this means he was enabled to perforate even an imperforate nostril. His experience justified him in urging the adoption of this method as vastly superior to the now generally received practice of perforating the septum. Dr. Jarvis then described his manner of removing polypi by means of the *éraseur* and concluded by summing up some of the advantages claimed for his methods, among which were the comparatively slight pain and inconvenience to the patient, the ease with which the operations could be performed, the small amount of hemorrhage incident to them, and the very successful results to be obtained. The surgical procedures which he advocated, he contended, were, therefore, greatly superior to the barbarous method of evulsion as he termed it, the application of the ligature and injection of strong acids, which sometimes left a sloughing mass which was most offensive to a sensitive patient, and operations by means of the galvano-cautery, which were very complicated and not infrequently unsatisfactory in their results.

The subject now being open for discussion, Dr. ELLSBERG stated that he believed the surgical treatment of nasal catarrh to be entirely of American origin.

About twenty years ago he had first tried the method of scarification at the suggestion of the late Dr. Horace Green. Finding, however, that there was apt to be excessive bleeding, and that he did not cure a very large proportion of his cases, he abandoned this, and resorted to the use of strong acid for the destruction of hypertrophic tissue. He soon gave this plan up, and then he attempted the mechanical removal of such tissue. He commenced by using the forceps, and he supposed that altogether he had devised as many as twenty or twenty-five different kinds of forceps and scissors for the purpose. Some twelve years ago, while in Dublin, he had first employed a wire snare, which was lent him by Sir William Wild, who had used it for removal of what he supposed to be a nasal polypus, but which he (Dr. Ellisberg) believed to be really a polypoid hypertrophy. Since then he had resorted to evulsion to a considerable extent, and he could not agree with Dr. Jarvis that it was such a barbarous, cruel, and bloody procedure if it were performed by a careful and prudent surgeon with the parts properly illuminated and well dilated. Dr. Jarvis's snare he thought a very excellent instrument. It was, no doubt, quite as good as any other; but he did not see any special superiority about it. In regard to the transfixion needles he had found that there was very great danger of lacerating adjacent tissues in introducing them, and he had now come to use thin-bladed transfixion forceps instead of these, especially in anterior hypertrophy. By allowing the forceps to project a little he could get the wire over the part to be removed much more readily than when he used the needles. The tape-holders, he thought, were not much of an improvement, as he had found that he could loosen the tape when desired more readily by simply untying it in the ordinary way. The little clips were apt to become covered with vaseline or other mucuous substance used for facilitating the operation, and thus so slippery that it was almost impossible to unfasten them. As to the scissors exhibited he did not think they differed materially from those in general use.

Dr. GOODWILLIE said that the nostrils had been well termed the gateway of the lungs, and that the immense quantities of air which passed through them were modified to a certain extent in the passage. It was the important function of the muciparous glands to keep the nostrils moist, and in any operation in these parts, therefore, he thought that great care should be taken to preserve as many of these glands as possible for the supply of the secretion to moisten especially the posterior nares. If the growth to be removed was pedunculated, he considered the *écraseur* the best means to employ, but if it were not, he preferred scarification by means of the galvano-cuttery knife. In deviation of the septum he believed it was generally necessary to remove a portion of the septum, and that nothing short of this would afford the desired relief. There was exceedingly apt to be exostosis in such cases, and when this was present the use of other instruments than the *écraseur* was demanded.

Dr. BOSWORTH remarked that for a considerable time past he had had a growing conviction, which was now a positive one, that the only common sense and satisfactory method of treatment of the conditions described in Dr. Jarvis's paper was by means of surgical procedure. The hypertrophy met with was largely made up of connective tissue, and it was useless to attempt

to get rid of it by any less radical means. He had personally used the *écraseur* exhibited, and had secured better results with it than with any other that he had ever tried. He was disposed to differ somewhat with Dr. Goodwillie in regard to the frequency of exostosis. In his experience he had found it of extremely rare occurrence, but when it was present the *écraseur* would remove the bone with the greatest possible ease. In fact, the steel wire of Jarvis's instrument made it applicable in a large number of cases in which it had heretofore been impossible to use the *écraseur* successfully.

Dr. ANDREW H. SMITH said that he also had used this *écraseur* with success, and that he considered it a great addition to our means of treatment. He thought that neither Dr. Jarvis or Dr. Bosworth had laid sufficient stress upon the very great advantage of the rigid steel piano wire, which seemed to him the distinguishing characteristic of the Jarvis instrument. In the discussion to-night a fact of considerable importance seemed to have been lost sight of, and that was one to which he had referred in a recent paper of his read before the American Laryngological Society. When the nasal passages were obstructed, and the patient continued to breathe through the nose, the result was that there must be a lessening of the pressure behind the point of obstruction. In other words, a partial vacuum would be formed with every inspiration, and wherever there was a vacuum there would be of necessity a flow of blood toward it. There would be, consequently, a constant hyperæmia of the part, and from hyperæmia to hyper-secretion was only a short step. In many cases of hypertrophy he preferred the application of mono-chloro-acetic acid to any other treatment. The special advantage of this caustic was that the eschar made by it remained until complete cicatrization had taken place. He applied it by means of a narrow, flat probe of hard rubber, which was wrapped with cotton, on one side of which cerate was smeared, so that the acid should touch only the parts desired.

Dr. BOSWORTH, speaking briefly a second time, said that whenever it was possible to use the snare, he preferred it to any other means of treatment; but if this was not available he agreed with Dr. Smith that the acetic acid was a most excellent application.

Dr. M. J. ROBERTS thought that from the standpoint of the general practitioner the instruments and methods of Dr. Jarvis commended themselves for their simplicity, and believed that any physician of average intelligence would be able to use them successfully in cases where the trouble was located anteriorly. If the posterior nares were affected, of course a greater amount of special skill was required in their application.

Dr. LINCOLN thought that the instruments and methods under discussion afforded a striking illustration of the progress which had been made in this department of medical science during the last few years. He had employed them himself and considered them infinitely preferable to some of the measures formerly in vogue. At the same time, he did not think that the opinion ought to go forth that these were the only efficient means of treating the class of cases alluded to in the paper. The procedures advocated by Dr. Jarvis were most excellent, and were no doubt to be preferred in a certain proportion of cases; but it ought not to be forgotten that there were other methods which were equally successful and which were indeed better in some instances. No one method was of universal ap-

plication, and among those agents which he had found of the greatest service were the galvano-cautery and chromic and acetic acids.

DR. BEVERLEY ROBINSON was inclined to think that the use of the snare was somewhat more difficult, as well as painful, than its advocates would have us believe, and said that he had found that in order to remove a growth by this means without much hemorrhage required quite a long time, — from half an hour to an hour. Even when this long time was occupied, the hemorrhage was very considerable, and in one case that he had had he thought it proper to keep the posterior nares plugged for twenty-four hours in consequence of this. The snare in his hands had also proved more painful than the galvano-cautery, so that he was scarcely willing to admit that this instrument was so greatly superior to the latter.

DR. JARVIS, in bringing the discussion to a close, remarked that in neither Hilton's nor any other of the snares previously in use was there employed the finely tempered steel piano wire of his instrument. He had found that all wires which were simply annealed gave way with the strain which it was necessary to impose upon them, and said that it was about three years ago when it occurred to him that it would be well to try the piano wire. As to the slipperiness of the tape-holders to which Dr. Ellsberg had alluded, this could easily be obviated by having the sides of the clips roughened. In regard to the desirability of sparing as many muciparous follicles as possible, he thought Dr. Goodwillie was mistaken. Pharyngitis sicca might be a primary affection instead of a secondary one, and he considered that there was no danger whatever of producing dryness of the nostrils by the methods he advocated. Even if all the other muciparous follicles were destroyed, those of the superior meatus, which was never reached in these operations, were abundantly able to supply all the moisture that was needed. As to the profuse hemorrhage of which Dr. Robinson had spoken, he thought that gentleman had been unfortunate in getting hold of one of those troublesome cases of hæmorrhagic hypertrophy sometimes met with. Then, perhaps, sufficient attention had not been paid to certain little details which assumed importance in such cases as these. There was often a slight tearing at the close of the operation, and it was Dr. Bosworth who had first pointed out the advantage of leaving the divided tissues *in situ* for a time, in order that hæmorrhage might be avoided. A much longer time than Dr. Robinson had suggested was also necessary for the satisfactory performance of the operation in these hæmorrhagic cases, and he mentioned one in which it had taken him four hours. Dr. Jarvis closed his remarks with a statement of his objections to the galvano-cautery.

The next order of the evening was the presentation by DR. L. L. SEAMAN of

#### A NEW APPARATUS FOR THE TREATMENT OF FRACTURE OF THE PATELLA,

which had received the indorsement of the late Dr. James R. Wood and other well-known surgeons. It consisted of two crescent-shaped pads, applied above and below the patella, which were kept in position by means of strips of adhesive plaster, and the extremities of which were attached by catgut strings to two bands of raw hide encircling the limb above and below the knee, the catgut being fastened to movable nuts. These

raw-hide bands were moulded over plaster casts so as to fit the parts accurately, and were connected with each other by means of steel rods on the inner and outer aspect of the limb, which were jointed in the centre, and could be kept bent at any desired angle by means of a lock and key. When tension was made upon the pads by means of the screw a pressure forward and downward was excited, which was sufficient to completely antagonize the quadriceps femoris muscle. One great advantage of the apparatus was that the patient could walk about immediately after it was applied.

### Recent Literature.

*A Treatise on the Science and Practice of Medicine, or the Pathology and Therapeutics of Internal Diseases.* By ALONZO B. PALMER, M. D., LL. D., Professor of Pathology and Practice of Medicine and of Clinical Medicine in the University of Michigan. New York: G. P. Putnam's Sons. 1882.

This is undoubtedly the first volume only of a treatise on the subjects indicated on the title-page. The purchaser and reader is, however, nowhere directly informed of that fact, and we must confess it was not until we had read the table of contents carefully without finding some very important diseases, and assured ourselves that the last page in the table of contents corresponded numerically with the last page between the covers, that we became aware that at least another volume would be necessary to complete the work. We then found General Pathology, General Diseases, Diseases of the Organs of Digestion and Assimilation, on the back of the cover; otherwise neither cover, title-page, nor preface indicates that this is a first volume, and the heading, Table of Contents of First Volume, gives only very indirectly the information required.

Professor Palmer has undertaken this work, the preface tells us, at the request of former and of present students under his teaching. He considers the large number of foreign works reproduced and sold in this country an indication that the wants of the reading American profession are not fully supplied by the few domestic treatises on the practice of medicine we now have; that habits and the particular surroundings of the people, as well as race and climate, produce differences in diseases requiring modifications of treatment; that descriptions of diseases and methods of treatment derived from consultation, practice, or experience in large metropolitan hospitals are not in all respects exact or applicable for cases occurring in an ordinary American village or country situation, where well-housed, well-fed, non-alcoholized people are seen in the beginning of their diseases. "The treatment adapted to the respective cases must be quite different, and the natural course of the disease must vary."

"The present work," the writer tells us, "has been prepared from the standpoint of an American physician, whose practice for years was in a village and farming community; who has become familiar with diseases in their beginning as well as in their advanced stages, both in a country and a city practice, more in the West, but also in the East; in the army, during the late war, as well as in civil life: from the standpoint of one who for years has been engaged in public, clinical, and hospital, as well as in private practice; who has long acted as a consultant as well as an attending physician, and whose observations have extended to

the large city hospitals of our own country; and who, years ago, as well as since this work has been in preparation, has made brief but careful observations in most of the medical centres of Europe."

Professor Palmer's credentials, as set forth by himself in the above paragraph, remind us not a little of those given by Professor Bartholow in his lately published *Practice of Medicine*, and certainly are very considerable. A morbid self-depreciation is evidently out of place in one who sees fit to write a new work on the *Practice of Medicine*, but an explanation of one's reasons and qualifications for so doing is apparently by no means contra-indicated.

For the pathology and histology of disease those who possess other works on the *Theory and Practice of Medicine* will not require the present book. To the aetiology and treatment of disease the writer's attention has been more especially devoted, and under these heads are to be found whatever there is in the work of personal observation and experience, and much that is really good. Good authors in several countries have been freely drawn upon, though not in all cases the latest authorities.

We cannot say that a physician already having several of the hand-books on the *Practice of Medicine* previously written and published in this country would really require Professor Palmer's; neither, on the other hand, would the student or busy practitioner, being restricted to a more modest library, be likely to be led astray should he have to rely upon Professor Palmer alone.

We do not know how many subsequent volumes to expect, but suppose a second will finish the work. In the matter of type and paper the publishers' work is well done.

*Anæsthesia and Non-Anæsthesia in the Extraction of Cataract*, with some Practical Suggestions regarding the Performance of this Operation, and Comparative Statistics of Two Hundred Cases. By HASKET DERBY, M. D., etc. 1882. Riverside Press. 32 pages.

In this little pamphlet the arguments in favor of non-anæsthesia in cataract extraction are well presented, and enforced by the statistics of two hundred cases; one hundred with, one hundred without, anæsthesia. The author has changed his practice of late years, and not as to the employment of anæsthesia only; he has also abandoned the use of mydriatics before the operation, in which, we believe, he is in general agreement with other operators, and has adopted the plan of first opening the eye at a much later period after operation than is generally done.

No one, we presume, would employ anæsthesia if the steadiness of the patient under operation could always be assured; it is because this cannot be done that anæsthesia is resorted to. Dr. Derby admits that he makes use of it in "exceptional cases." He thinks, however, that, as a general rule, the patient may be persuaded to control himself sufficiently, and this may be agreed to. The difficulty is to decide in advance just which patients may be trusted, and which not. And even the experience he has acquired is insufficient always to determine this point correctly. It is said of the only patient whose behavior is mentioned, that he was "very restless during the operation, the performance of which was thus rendered unusually difficult."

It is perhaps only natural that, in setting forth the

advantages of a method which is believed in, there should be danger lest the counter advantages of a different method be unconsciously ignored or its disadvantages exaggerated, and this danger seems here not wholly to have been escaped. It is asserted that in profound anæsthesia the eye loses its tension, and the difficulty of removing cortical fragments is increased. True, but, on the other hand, the loss of tension lessens the danger of escape of vitreous. We are told that, to clear the pupil after removal of the main portion of the lens, with etherized patients, the eye "must often, if not always," be held by fixation forceps, etc. To this we can only say that it does not accord with our experience.

The statistics given apparently show in a striking manner the superiority of non-anæsthesia and the other modifications in treatment adopted. We say apparently for several reasons. It is well known that statistics are often deceptive. Dr. Derby himself says that the loss in the series with anæsthesia (9) was unduly large, and that it cannot be claimed that the loss in the series without anæsthesia (1) will be maintained. In the statistics given by Arlt, "one of the first of living operators," we find great differences in different years in the percentage of losses by the same method of operation, the proportional variation being even slightly greater in two of the years than that in the two series here presented, and, as the numbers given by Arlt are larger, this is all the more remarkable.

The one hundred cases operated on without ether are said not to have been selected. We cannot doubt the honesty with which the statement is made. Yet to our mind there was a certain selection. It appears that during the time over which this series extends there were some exceptional cases in which ether was given. These must have been in part, if not all, excitable patients, with so little self-control that they could not be trusted to remain quiet during operation. But such patients, even with anæsthesia, would, other things being equal, not be likely to do as well as individuals with good power of self-control. It was to the benefit of the general result, therefore, to exclude them from the series. Finally, one man, whose eye was lost, was excluded from the series for reasons which to Dr. Derby were a sufficient justification, but which hardly appear so to us. The condition of the eye on discharge, on the fifteenth day, is described as like that of the case of failure, which was included, and which was also discharged on the fifteenth day; that is, the pupil was blocked with corticalis, but there was good perception of light. In both these cases there soon came on severe inflammation, and the eyes were lost. The man rejected from the list did not report as he had promised, yet it is only a supposition that there was neglect of proper care for the eye on his return home.

But, although we are unable to agree with all the conclusions of the author, we have no hesitation in saying that the careful attention to the details of the operation and treatment, and the avoidance of all unnecessary instrumental interference, upon which he insists, are of the greatest importance. Dr. Derby has undoubtedly skill and experience, and may be able, in general, to decide correctly what patients are suitable for operation without anæsthesia and to overcome the difficulties which restlessness presents; we are convinced, however, that if it were the general practice to operate without an anæsthetic the results would not be as favorable as they are now.

## Medical and Surgical Journal.

THURSDAY, JUNE 8, 1882.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.

HOUGHTON, MIFFLIN AND COMPANY,  
No. 4 PARK STREET, BOSTON, MASS.

## AN INQUIRY INTO THE PHYSIOGNOMY OF PHTHISIS BY THE METHOD OF COMPOSITE PORTRAITURE.

In the JOURNAL of April 20th was a short editorial notice of a suggestion by Francis Galton, F. R. S., for the establishment of anthropometric laboratories, a subject the outlines of which presented themselves first to the mind of that writer in the course of his experiments with "composite portraits." His first article on Composite Portraits appeared in the *Journal of the Anthropological Institute*, 1878,<sup>1</sup> and another entitled Composite Portraiture in the *Photographic Journal*, June, 1881.

This method of composite portraiture consists in throwing upon a photographic plate, disposed in a special form of camera, the images of several negatives in succession, an equal fraction of time being given to each instead of the whole time to one. A single plate that has been exposed to several negatives yields a so-called composite. Several of these composites may in their turn be exposed to another plate under similar circumstances as if they were ordinary negatives, the result being called a "co-composite." Several "co-composites" may again be combined, producing a co-co-composite, and this process of combination continued.

Mr. Galton, in conjunction with Dr. F. A. Mahomed, undertook an inquiry into the physiognomy of phthisis, based upon this method of composite portraiture, and the results are published as a paper in the last volume of Guy's Hospital Reports. Their object was to prove or disprove, so far as one series of investigations in regard to one form of disease, and that the most common in civilized countries, could do it, the old doctrine of diatheses or "temperaments;" the belief, in other words, that certain physical conformations indicate predispositions to certain diseases, which has always held a prominent place in medicine from early times. In regard to this doctrine these writers say, in the paper referred to, "Of late years this doctrine has been repudiated by many of our most able teachers, though, on the other hand, it still receives the powerful support of some of the most distinguished and experienced of our physicians; so that what heretofore has been generally accepted has now become a much-disputed question. The objections that have been raised against the doctrine are chiefly these: that it is founded on the utterly false and erroneous doc-

trine of 'humors,' held by physicians in the dark ages; that it is, therefore, only a relic of false traditions; and lastly, that it is not supported by any modern scientific observations, and that the statements of 'general impressions' made in support of it are those of impressions prejudiced by traditional beliefs. In reply to these objections it may be said that the facts observed by the earlier physicians were probably correct enough, and that only their explanations and theories were wrong; thus, certain facts in connection with the physical characteristics of individuals in connection with certain diseases they sought to explain by false theories; the facts, nevertheless, remain true. The objection, however, that this doctrine is only supported by personal impressions still holds good." As no diathetic types are probably more commonly recognized, either rightly or wrongly, than the so-called tubercular or strumous, and as persons presenting the physical characteristics attributed to these diatheses are believed to be especially predisposed to phthisis, it appeared to Messrs. Galton and Mahomed that this belief might be put to the test by means of the method of "composite portraiture," that they might be able to ascertain whether there are any facial characteristics common to any large proportion of cases of phthisis. Beginning in January, 1881, by May they had accumulated 442 portraits of patients suffering from phthisis between the ages of fifteen and forty years, of whom 261 were males and 181 females. These patients were taken at random from among the in and out patients of Guy's and of the Brompton and Victoria Park Hospitals, by different medical officers, the extent, duration, form of onset of the disease, hereditary taint, and preceding conditions being noted on cards distributed for that purpose. For comparison with these 100 male and 100 female patients, taken without selection from the wards and out-patient rooms at Guy's Hospital, but not suffering from phthisis, were photographed.

The individual portraits of the patients suffering from phthisis, compared in a general way, did not disclose any characteristic faces, nor did they seem to differ much from any group of ordinary patients. In forming composite portraits of different sets of these 261 male and 181 female phthisical patients, especially of those having a strong hereditary taint and in advanced stages of disease, as well as of sets of cases taken absolutely without selection, the results obtained, Messrs. Galton and Mahomed report, "appear to lend no countenance to the belief that any special type of face predominates among phthisical patients, nor to the generally entertained opinion that the narrow, ovoid, or 'tubercular' face is more common in phthisis than among other diseases. Whether it is more common than among the rest of the healthy population we cannot at present say. It is true that, taking both sexes together, we find 14.3 per cent. of faces that may be classed as 'narrow ovoids,' and 9.3 per cent. that come under the head of 'broad faces with coarse features,' making in all 23.6 per cent. of our cases which may be grouped under one or other extreme departure in either direction from the normal

<sup>1</sup> Reprinted in Nature.

average, but we doubt if this is more than could be found among the general population. Our results are, therefore, negative, but it may be they are no less valuable; although we commenced our investigations with the expectation of establishing a 'type' on a firm foundation, we shall be little less satisfied with them if they have succeeded in refuting an error. Although these conclusions would seem to indicate that there is no foundation for the belief that persons possessing certain physical characteristics are especially liable to tubercular disease, yet it may hereafter be proved that some explanation of the doctrine may be found in the course of the disease when it attacks such persons."

Inquiries into this and kindred points are reserved for future investigation, which it is thought may possibly demonstrate that, though much error has been accumulated around the doctrine of "diatheses," it nevertheless contains a nucleus of valuable truth.

#### SUFFOLK DISTRICT MEDICAL SOCIETY.

##### THE SECTION FOR CLINICAL MEDICINE AND PATHOLOGY.

On the evening of May 27th the meetings of this branch of the Suffolk District Medical Society for the current medical year were brought to a termination. It seems quite proper at this time to review the work of the Section, both in order to ascertain its mistakes and deficiencies as well as for the encouragement which the experience of this year offers for the success of future efforts.

The division of the general Society of this district into sections, representing to a certain extent the more important departments of medical science, had long been considered desirable. It finally became necessary for the healthy and vigorous development of society work among physicians; and from the more definite character of the labors which might thus be undertaken and prosecuted by each department for the common interest and advancement of all much was hoped. The general Society was too general in its design and too ample in its scope to bring out successfully that which was best in its special departments. The attempt to establish special subordinate branches of the Society was made some years ago, but for a variety of local reasons the efforts in this direction were crowned with only indifferent success. The various smaller medical societies or clubs in Boston at that time looked somewhat coldly upon the undertaking, to which they afforded neither encouragement nor assistance. The general Society still assembled at stated intervals, usually once a month, during nine months of the year, and this was the only reunion for medical discussion accessible to a majority of the profession in this city. The subjects presented to the Society at these meetings were always interesting, but of necessity were naturally confined to certain divisions of medical practice, which were more interesting to a part of the Society than to that body as a whole.

The first attempt at a division of the general district Society was carried into effect in 1868; at this time eight subordinate sections were established, devoted to (1) Anatomy and Physiology, (2) Medical Pathology, Clinical Medicine, and Hygiene, (3) Obstetrics and Diseases of Women, (4) Chemistry, Pharmacy, and Materia Medica, (5) Surgery and Dentistry, (6) Ophthalmology, (7) Psychology, (8) Microscopy. These were expected to attend to any matters referred to their several departments by the general Society, and to report independently of such direction upon any matters of interest to the general body of the Society.

The first meeting of the Section for Medical Pathology, Clinical Medicine, and Hygiene, since contracted to "Clinical Medicine and Pathology," was held at the house of Dr. H. I. Bowditch, who was elected permanent chairman, some time in 1868, with a membership of twenty-eight.

The meeting was called "to consider the subject of the instrument called the Hydroleik."

During the autumn of 1868 three meetings were held at the house of Dr. Bowditch.

The succeeding meeting is dated April 10, 1869, and was also held at Dr. Bowditch's house.

There is no record of any meeting from this time until October 25th of the same year, when a single meeting was called at the house of the chairman.

A hiatus now occurs in the records until December 21, 1874, when the minutes state that "the Section met at the house of the secretary for the first time in five years," and was attended by four members, namely, the late Dr. E. H. Clarke, Drs. J. B. Upham, J. B. Webster, and H. K. Oliver. The subject for the consideration of the Section at this meeting was the connection of the rain-water spouts of dwellings with the sewers in the streets, as was at that time proposed by city ordinance. This measure was at first vigorously opposed by a portion of the profession, on the ground that the air of chambers and sleeping-rooms would become dangerously contaminated by the escape of sewer gases from the spouts at the eaves of the houses, and thus cause disease in the occupants of such rooms.

Another period of hibernation now intervened in the history of the Section, which slumbered in unbroken tranquillity until it was aroused May 14, 1881, by a call from Dr. H. C. Haven, the vigorous and efficient present secretary of the Suffolk District Medical Society. At this time only nineteen of the former members were still living, and of these two now reside far from Boston.

Through the efforts of Dr. Haven eleven members were at once added to the list; the first meeting, which was called with some uncertainty as to its success, proved a very interesting one, and it was the unanimous opinion of those present that the attempt should be made to reestablish the Section upon a substantial basis. At this meeting Dr. Bowditch, permanent chairman of the Section, presided, and papers were presented by Drs. F. C. Shattuck, E. G. Cutler, and A. N. Blodgett, in the discussion of which every member present took part.

The meetings of the present year have been seven in number and have been largely attended. The number originally intended was six, but the amount of material placed at the disposal of the secretary was so unexpectedly large that an extra meeting was necessary in order that it might all be presented. The interest in the Section has not abated during the season, and the list of those desiring membership was constantly increased until it now contains one hundred and thirty-two names. The meetings are held in the reading room of the Medical Library, though this apartment is far too small to accommodate so large a number. At the meeting in May, 1881, Dr. Bowditch was chairman, and Dr. H. K. Oliver secretary, and these two gentlemen continued to act until the meeting of December 3, 1881, when, not desiring to serve longer, they were succeeded by Dr. T. B. Curtis, as chairman, and Dr. A. N. Blodgett, as secretary. Before the next session of the Section the sudden death of Dr. Curtis rendered the chair again vacant, and the present chairman was elected.

Papers have been read before the Section during the past year by the following gentlemen: Drs. S. L. Abbott, J. B. Ayer, H. J. Barnes, H. J. Bigelow, A. N. Blodgett, Mr. Ernest W. Bowditch, Drs. H. I. Bowditch, Hall Curtis, E. W. Cushing, W. A. Dunn, S. H. Durgin, Thomas Dwight, G. M. Garland, S. W. Langmaid, G. H. Lyman, J. H. McCollom, F. Minot, Morton Prince, T. M. Rotch, F. C. Shattuck, and W. F. Whitney.

The names of those taking part in the discussions include those of many of the prominent and active physicians of Boston as well as some from other cities.

Several new instruments and appliances, as well as many pathological specimens, have been exhibited at these meetings, and a degree of interest has been aroused which promises much for the future. The chief defect in the Section as now organized is the comparatively slight encouragement offered to labors in the domain of pathology, either general or special. This is no new condition with the Suffolk District Medical Society. It has existed for many years.

Among the subjects of many excellent papers presented during the year just closed pathology was unrepresented. For the purpose of guarding against such a deficiency during the next year efforts have already been made to secure material of this character. Several gentlemen have already promised papers upon some subject connected with special pathology during the year 1882-1883.

It is hoped that some contribution in the direction of pathological research may be included in the programme of each meeting. The Secretary received a very flattering note from the Secretary of the Pathological Society of Philadelphia, asking for an exchange of Pathological Transactions between the two Societies, but was obliged to return the humiliating reply that neither Pathological Society nor Pathological Transactions existed in Boston. This is the more a matter for regret as it is wholly inexcusable.

One or two of the other Sections, especially that of Surgery, have been active and attended with interest.

In another number we shall hope to give some account of the work accomplished by them this winter.

There seems to be a tolerably general feeling that there are at present in Boston a greater number of small Medical Societies than is profitable for their individual welfare or for a really vigorous and stimulating discussion of the theory and practice of the profession.

#### MEDICAL NOTES.

—The daily papers have contained rumors of resignations in the Harvard Medical School, which we abstain from commenting on until duly authenticated.

#### NEW YORK.

—On the evening of May 15th the first annual meeting of the Charity Organization Society of the City of New York was held. This Society has been formed on the same general plan as similar societies already in successful operation in a number of other cities, and its existence is due to the State Board of Charities, who, in October last, passed a resolution to the effect that, in view of the fact that there was no system of cooperation by which the various independent charitable associations in the city could receive definite mutual information in regard to the work of each other, and that without some such system there was an unavoidable waste of effort, and pauperism and imposture were liable to be encouraged, the New York City members of the Board should be appointed a committee to take such steps as they deemed wise to inaugurate a system of mutual help and cooperation between such societies. Among the fundamental principles of the Charity Organization Society are, that every department of its work shall be completely severed from all questions of religious belief, politics, and nationality, and that the Society shall not directly dispense alms in any form. Among the objects of the Society are the following: To investigate thoroughly, and without charge, the cases of all applicants for relief which are referred to the Society for inquiry; to provide visitors, who shall personally attend cases needing counsel and advice; to obtain from the proper charities and charitable individuals suitable and adequate relief for deserving cases; to procure work for the poor; to repress mendicancy and prosecute impostors; and to promote the general welfare of the poor by social and sanitary reforms, and by the inculcation of habits of providence and self-dependence. Among the speakers at the recent meeting of the Society was Mayor Grace, who said that he had been at a loss to account for the increase of paupers of late in New York, but now thought it was abundantly explained by the fact that Boston and Philadelphia had for some time been provided with charity organization societies, while New York had hitherto been without such an institution.

—At the last meeting of the Section of Theory and Practice of Medicine of the Academy of Medicine papers were read by Dr. L. Putzel, on a case of hemiplegia, illustrating the connection of descending degeneration and atrophy of the anterior horn of the

spinal cord, and by Dr. A. McLane Hamilton, on a case of word-blindness, with loss of taste and sense of localization.

—The Board of Health have sent communications to both branches of the State Legislature, protesting against the passage of a bill providing for the demolition of the reception hospital for contagious diseases at the foot of East Sixteenth Street. Accompanying the protest to the Senate was a letter signed by Commissioners Chandler and Woolsey Johnson stating that although the protest to the Assembly (which was sent previously) had been accompanied by a letter from the mayor requesting a special hearing, no such hearing had been granted, and that it was a matter of vital importance to the city of New York to have a properly located reception hospital for contagious diseases, so that until some other suitable location could be secured it would be madness to deprive the city of the only one that it now had. The letter furthermore stated that the present site at the foot of East Sixteenth Street was probably further removed from dwelling-houses than any other site which it would be possible to secure, and that no evil had ever resulted to residents of the east side from the presence of this hospital.

The Sanitary Reform Society has also sent a protest to Albany upon the same subject, and against the following bills now before the Legislature, in addition: An act providing that the Boards of Health of New York and Brooklyn shall not prohibit the use of vitrified glazed pipe or tile for drainage of buildings, and an act which provides that every person who shall sell, or offer for sale, any milk from which the cream, or part of the cream, has been removed, shall distinctly represent it as such, and mark, in letters not less than one inch in length, on the outside of every can containing such milk, the words "skimmed milk." The latter bill, the Society urges, will in reality legalize fraud in milk, and open the doors to the increased sale of poor milk.

—The sanitary inspectors have just discovered a small-pox nest in a tenement-house on Baxter Street, which is crowded with Italians; there being as many as sixteen families, making up a population of over one hundred altogether, in the house. The premises were in a wretchedly filthy condition, and in the first apartment visited, which, although only about twelve by fifteen feet, was inhabited by no less than eleven persons, a man was found in the suppurative stage of small-pox. In another room, hardly less crowded, a young woman was suffering from the disease, and in still another, a little child. All of the cases were sent to the reception hospital, and the house, after being disinfected, was quarantined. It is claimed by the inspectors that in places of this kind, while they are examining the lower floors the inmates sometimes escape through the roof with such persons, and keep them in adjoining houses until the visit is concluded; a practice which, of course, adds very materially to the spread of contagious disease.

—The public baths opened on the first of June. There are each year increasing in popularity, and

would be even more extensively used than they are if the accommodations were more ample. They have been utilized to their fullest capacity of late, and that more persons have not resorted to them is simply because the baths have been inadequate to meet the demand upon them. In 1878 the number of bathers was 2,457,537; in 1879, 2,881,279; and in both 1880 and 1881 about 3,500,000, or an average of 30,000 a day.

—On the morning of the 18th of May Dr. Hervey Kendall was found lying in an insensible condition, with a bullet-hole between his eyes, in a meadow near the County poor-house cemetery of Syracuse. From the implements by his side it was evident that he had been upon a grave-robbing expedition, but the manner of his shooting still remains a complete mystery. On the following night he died from the effects of the injury, without recovering consciousness. It is stated that he was graduated from one of the Eastern colleges last summer, when he came to Syracuse to practice, and that since that time he has been in the habit of furnishing subjects for dissection to the medical school in that place. Lately, however, he is said to have quarreled with the authorities of the institution, and has been supplying some other college with subjects. The opinion prevails in the neighborhood that he was probably wounded in an affray with another party who had visited the locality on a similar grave-robbing errand.

—The body of a man found drowned on the 26th of May in the Hudson River at the foot of Twenty-Fifth Street has been recognized as that of Dr. J. Scott Payne, a practicing physician of Rahway, New Jersey. He had been missing since the 10th of May, on which day he came to New York on business, and when last seen alive he was on his way to one of the New Jersey ferries. It is supposed that he fell overboard from the ferry-boat while crossing the river.

—The branch hospital and dispensary at the corner of Sixty-Seventh Street and Lexington Avenue, presented by Mrs. Anna Ottendorfer to the German Hospital, was formally dedicated and opened on Saturday, May 27th. The building has been erected at a cost of \$45,000. There was also celebrated at the same time the twenty-fifth anniversary of the opening of the dispensary connected with the hospital.

#### PHARMACEUTICAL NOTE.

—Boro-glyceride, as described by Professor Barff in the *Journal of the Society of Arts*, March 31st, as a preservative was required in the rather high proportion of one ounce to a quart of cream. The continued ingestion of such a proportion with food is of importance considering that it is asserted concerning both the original ingredients that they act, deleteriously when taken in such quantities. It also appears that aqueous solutions would require to be used while hot, for the compound is decomposed into boric acid and glycerine in the presence of water, and the acid crystallizes out on cooling. — *Pharmaceutical Journal and Transactions*, April 29, 1882.

## Miscellany.

## THE ADMISSION OF WOMEN TO THE MASSACHUSETTS MEDICAL SOCIETY.

MR. EDITOR, — At the last meeting of the Society it was voted, on motion of Dr. Hodgdon, that "when the Society adjourn it do so to meet on the Tuesday preceding the next annual meeting at four o'clock p. m., the secretary to notify the members of such meeting." It was explained that the object of such meeting was the discussion of an amendment to the By-Laws looking toward the admission of women to the Society.

With a view to an accurate appreciation of the present status of this question, it seems desirable to recapitulate briefly the past action of the Society upon this topic.<sup>1</sup>

February 2, 1852. The councilors (on the question of the admission of women to the Society) voted, the censors are directed to examine males only, and the Massachusetts Medical Society *might assume any responsibility or expense which the censors might incur.*

June 4, 1867. To a question from the trustees of the Massachusetts General Hospital the councilors voted that it was inexpedient for our State medical schools or the hospital to admit female medical students. The vote stood, seven affirmative, forty-nine negative.

October 7, 1872. The censors for Suffolk asked what they should do, as they had been requested by a female physician to allow her to be examined for a license to practice and for admission to the Society. A committee was appointed to report February, 1873.

February 5, 1873. Four of the committee were in favor of, one against, granting the request. After discussion the report was recommended to the same committee, with directions to take legal counsel as to the question whether, as the law now stands, women had a right to ask admission.

June 3, 1873. Committee reported in substance as follows from their counsel, E. R. Hoar and George Putnam, Esq. : —

(1.) The Society has a right to say that only males shall be admitted to a license and membership.

(2.) It has never done so by any By-Law.

(3.) That in the absence of such By-Law the censors have to decide whether sex is a disqualification for the medical or surgical practice.

(4.) That in the absence of any By-Law from the Society, if any woman be licensed by the proper officers she is thereby entitled to membership. The censors may reject a woman if they think sex a disqualification for medical and surgical practice.

Upon this report the councilors voted to instruct the censors not to admit women. Carried by a small majority.

June 8, 1875. On motion, it was voted to choose a committee of five to report whether duly educated women cannot receive the rights and privileges of membership.

October 5, 1875. A majority of this committee reported in favor of examining males and females without distinction. The minority objected to such examination. A long discussion ensued, and an indefinite postponement of the whole matter was carried by a very close vote.

June 11, 1878. A resolution came to the councilors from the Middlesex South District Society requesting that well qualified female practitioners should after examination be admitted. A committee of five was chosen to report at the next meeting.

June 10, 1879. A year afterwards the committee reported that of the largest number of the committee which had attended any meeting the members were equally divided in opinion. Voted to recommit to the same committee, and with a request to report at the next meeting.

October 1, 1879. The majority of the committee advised no action. The minority reported as follows, that the censors of the Massachusetts Medical Society should be instructed to admit women for examination. The councilors voted, 48 to 38, to adopt the minority report.

February 4, 1880. The censors of Suffolk protested against such instructions unless ratified by the Society. After some discussion, during which a proposition was made that an appropriate By-Law should be recommended to the Society, it was finally voted that the vote passed October 1, 1879, directing the censors of districts to examine women, be rescinded!

<sup>1</sup> Dr. J. R. Chadwick, as quoted by Dr. Bowditch, in the Boston Medical and Surgical Journal, vol. civ., page 291, September 29, 1881.

February, 1881. The subject was again brought up by a councilor, and it was laid upon the table.

At the annual meeting of the Society held on June 9, 1880, Dr. Bronson offered the following : —

*Moved,* That when this meeting adjourns, it do so to meet at the place of annual meeting on Tuesday preceding the annual meeting of 1881, at four p. m.

Dr. Bronson explained that his object in making the motion was to present an amendment to the By-Laws by which women should become eligible to membership of the Society. The motion was adopted.

This meeting was held on June 7, 1881, and a report of the proceedings published in this journal (June 16, 1881). Before adjourning a committee was appointed, in accordance with the vote of the Society, to act with a committee of the council and report after taking legal advice, if necessary, —

(1.) Whether the Society has the power to originate an amendment to the Constitution or By-Laws.

(2.) Whether it is necessary to publish a new code of By-Laws.<sup>2</sup>

The clauses of the Act of Incorporation and of the By-Laws thus submitted to the committee for interpretation are as follows : —

III. The Fellows of the Society shall have full power and authority to make and enact such rules and By-Laws, for the better government of the Society, as are not repugnant to the laws of this Commonwealth; and to annex reasonable fines and penalties to the breach of them, not exceeding the sum of twenty pounds.

IV. The Fellows, at their annual meetings, whenever such a number shall be present as the regulations of the Society may require, may revise, alter, enlarge, and repeal the By-Laws of the Society, as the major part of the Fellows present may see fit, and not otherwise.

This authority to *originate By-Laws* is in no wise curtailed by the only section of the By-Laws bearing upon the subject : —

## ALTERATION OF BY-LAWS.

XXXIII. All proposals for alteration of the By-Laws shall be stated in writing.

No alteration of a By-Law shall take effect until it has received the concurrent vote of the councilors and the Society; and no amendment affecting the import of said alteration shall be engrained on it without a like concurrent vote. But the councilors or Society may at a special meeting, notice having been given at a previous stated meeting, or in the call for the meeting itself, adopt rules and orders for their better government, or alter or amend, or annul, the same; but these rules or orders shall not be temporarily suspended at any meeting except by an affirmative vote of at least three-fourths of the Fellows present.

The Society shall consider, and act on, By-Laws at adjournments of anniversary meetings only, and not on the days of said meetings.

At the meeting of the councilors held on October 5, 1881, the committee reported as follows<sup>3</sup> : —

"It is not necessary to formulate a new code of By-Laws, it having been ascertained from the records of the council and Society that the last edition contains and includes all the By-Laws that are now in force."

The committee recommended, with reference to the other matter before them, that the following be adopted as an amendment to the present rule governing such actions : —

"In all changes of the By-Laws, requiring, as they do, a concurrent vote of the councilors and Society, the action of the councilors shall precede that of the Society; but it shall be competent for a Fellow at any meeting of the Society to propose any alteration of any By-Laws, and the said proposition shall at once be referred to the councilors, and, in case of its

<sup>2</sup> The wording of these two questions has been slightly modified in order to make them more explicit.

<sup>3</sup> Boston Medical and Surgical Journal, vol. cv., page 376, October 20, 1881.

adoption by the councilors, it shall be submitted again to the Society for final action."

In this report the committee clearly fails to give a direct reply to the first question submitted to it, but from the fact that it recommends the passage of a By-Law granting to the council the exclusive right to take the initiative in amending the By-Laws, the only inference is that the committee do not find that the council has that prerogative under the present By-Laws.

The view that the Society has never surrendered this right is supported by precedent. "In 1870 Dr. Sullivan, of Malden, proposed in the Society a change of By-Laws, and Dr. H. R. Storer moved to adjourn for five minutes. This was done. The change was discussed and carried at the adjourned meeting. It was sent to the councilors and carried on motion of Dr. Bigelow, seconded by Dr. Ellis."

It has been claimed that this action should not be regarded as a precedent for the reason, as alleged, that the vote was carried in the Society amidst "much confusion." It has not been shown, however, that the council was in "much confusion" when it received the amendment from the Society and took concurrent (though subsequent) action, whereby the amendment became and is now a legal provision of our code of By-Laws.

As the Society will certainly discuss the expediency of admitting women to membership at the adjourned meeting on the afternoon of Tuesday, June 13th, and may pass an amendment to the By-Laws; and as the council have taken no action upon the matter, and does not meet again until after the adjourned meeting of the Society, it is important that a definite statement of its opinion upon the subject of priority of action should be received from the committee in its report to the Society, which may properly be called for at the adjourned meeting.

Priestley's maxim, that we "should never accept any man's opinion, however respectable," certainly applies to so intelligent a body as the Fellows of the Massachusetts Medical Society, yet the fact that all the other State Societies to whom application has been made, have admitted women to their ranks, gives respectability and weight to the arguments in favor of this measure.

In October, 1880, I sent a circular to the secretary of every State Medical Society in the Union asking for official replies to the following questions:—

(1.) Have any applications for membership been made by women?

(2.) Has any action been taken on such applications?

(3.) Have any women been admitted to the Society?

(4.) What are the names and addresses of the female members, and what are the dates of their admission?

In the replies from eleven States—New Jersey, North Carolina, South Carolina, Virginia, Maryland, Georgia, Mississippi, Louisiana, Kentucky, Arkansas, and Missouri—the secretaries stated that no women had ever applied for membership. To this number may be added two States, Florida and West Virginia, whose list of members, as published in the Transactions of their respective Societies for 1881, contain no names of women, and I have been unable to find any record of their rejection in any volume of their Transactions. We have consequently thirteen State Societies to which women have never applied. These, it will be observed, are nearly all Southern States.

In the Wisconsin State Medical Society the "con-

sors refused to admit a woman in 1875 on sole ground that her credentials did not conform to the requirements of the Society for all members of either sex. Nothing in the Constitution or By-Laws to prevent the admission of women." Secretary.

The other secretaries made replies which may be tabulated as follows, with certain additions derived from the last published Transactions of the Societies:—

|                           | Year when first admitted. | No. of Female Members in 1881. |   |
|---------------------------|---------------------------|--------------------------------|---|
| Maine .....               | 1875                      | 4                              | This Society is made up entirely of delegates from County Societies, which may contain other women who have not been elected delegates. Secretary reported two names, but Transactions for 1881 give names of three women.  |
| New Hampshire .....       | 1875                      | 2                              |   |
| Vermont .....             | 1874                      | 3                              |   |
| Rhode Island .....        | 1880                      | 3                              |   |
| Connecticut .....         | 1880                      | 3                              |   |
| New York .....            | 1875                      | 42                             | This Society is made up of delegates from County Societies. Only one woman has actually been elected delegate; the larger number is placed in the table because it is my purpose to show how many women are practicing in the different States with full recognition of the local organizations. Forty-two women are members of the County Societies. |
| Pennsylvania .....        |                           | 8                              | Society of delegates. Only two women are reported by the secretary as having been delegates. The Transactions for 1881 contain the names of eight women.  |
| Tennessee .....           | 1880                      | 1                              | "Many years ago, without any application on the part of the women, action was taken adversely to them. This was rescinded at a subsequent meeting." Secretary.  |
| Ohio .....                | 1875                      | 5                              |   |
| Michigan .....            | 1872                      | 8                              | Seven reported by secretary. Transactions for 1880 give names of eight.   |
| Kansas .....              | 1872                      | 3                              |   |
| Iowa .....                | 1872                      | 2                              |   |
| Minnesota .....           | 1879                      | 6                              |   |
| Indiana .....             | 1876                      | 5                              | Society of delegates. Four reported by secretary. Transactions for 1880 contain names of six women. Application of a woman for admission in 1878 was refused, but was voted unanimously in 1879.  |
| Illinois .....            |                           | 10                             | Three reported by secretary. Transactions for 1881 contain names of five women. Society of delegates. Transactions for 1881 give the names of ten women.  |
| Oregon .....              |                           | 5                              | No reply from the secretary. Numbers taken from names of women in Transactions for 1881.  |
| California .....          | 1855                      | 3                              | No reply from secretary. Taken from names in Transactions for 1878-1879.  |
| Seventeen Societies ..... | —                         | 115                            | Female members of State or County Societies.  |

From these data, derived almost entirely from official sources, several startling facts become evident.

(1.) In the first place no State Medical Society in the Union to whom women have ever applied for admission now shuts its doors in their faces, so far as my sources of information extend.

(2.) Seventeen State Medical Societies, representing the oldest and most enlightened communities on the continent, have given their verdict, without a dissenting voice, that sex is no disqualification for admission to their ranks.

(3.) The fact that one hundred and fifteen women have had their fitness to practice medicine acknowledged by the authorized censors of the medical profession of America effectually demonstrates that women are being generally recognized throughout the country.

This number does not, however, include all the graduates of accredited colleges who are now practicing in America. For instance,<sup>1</sup> of the 276 alumnae of the Woman's Medical College of Pennsylvania 32 have died, 23 are for various reasons not in active practice, 55 have not been heard from, and 166 are practicing medicine. Of 430 female graduates of various medical colleges 390 are known to be in active practice, 11 never practiced at all, and 29 practiced for a time and then retired.<sup>2</sup> The colleges referred to are the Universities of California and of Michigan, where coeducation exists, and four separate schools: "New England Female Medical College," Boston, Mass., which ceased to exist in 1874; "Woman's Medical College of Pennsylvania," in Philadelphia; "Woman's Medical College of the New York Infirmary," in New York City; "Woman's Medical College of Chicago." A new medical school for women has just been organized in Baltimore.

This brief array of facts has been hastily strung together without argument to aid the Fellows of the Massachusetts Medical Society in forming an intelligent opinion, based upon fuller knowledge than might otherwise be accessible to them.

It is an undoubted fact that many women are now practicing medicine in Massachusetts. The main question before our Society is whether it ought not to protect the public by distinguishing such as are fairly educated from ignorant and fraudulent practitioners, at the same time giving to those whom it finds qualified the advantage of a participation in the scientific exercises of the State and District Societies.

Very truly yours, JAMES R. CHADWICK, M. D.  
Boston, May 31, 1882.

#### A CASE OF LABOR AS DESCRIBED BY A POPULAR NOVELIST.

MEDICAL men who can scarcely find time to digest properly the material brought to them by their medical journals, or to do more than endeavor to grasp the new ideas evolved by their recent text-books, may desire to learn more of the class of reading which some of their patients indulge in, and to judge thereby of its possible influence upon diseased conditions.

This is deemed to be the only apology necessary for giving below what finds its most suitable place in the columns of a medical journal, the translation of a half dozen pages from a very recent and popular French novel, Emile Zola's *Pot Bouille* (pages 471-477). This novel can be found on the table of any dealer in foreign publications, alongside of Mme. de Staël or any other French work which a young person might desire to purchase for the purpose of improving his or her proficiency in the French language. The English translation is to be found with all booksellers, the realistic and graphic portions being in part omitted, but the references to the same preserved; so that it is of no use to one who reads for information of the style of the writer, and flat and unprofitable to one who reads for any other purpose, being merely a stimulant to curiosity to know what was omitted.

The plot is *nil*; the scenes lay in a respectable house with a series of flats, and with a young man who pro-

ceeds to attempt to debauch each available woman in succession. The seductions are conducted in a refined and elegant manner, but as a contrast to this there is a servants' floor, where obscenity and free comments upon such matters are indulged in. One of the characters is a young girl of fourteen years of age, who is very curious, and who obtains a large fund of information as to the sexual relations by looking through the keyholes of bedchambers, which information she illustrates practically upon her nurse by encouragement from the nurse.

Adèle is a servant who finds herself pregnant, but manages to conceal it from her mistress up to the last moment, and here begins what is certainly, from a medical standpoint, a remarkable description.

"On this evening Adèle went to bed about eleven o'clock. Her approaching period of labor was still to her in the uncertain future; she did not care to reflect upon it, but preferred to keep it out of her mind in the hope that in time it would all come right. Consequently she had made no preparations, was ignorant of the symptoms, incapable of recalling or calculating any fixed period, without any idea, without any project. She was only comfortable in bed, stretched out on her back. As it was quite cold, she went to bed in her stockings, put out the light, and endeavored to get warm. Finally she slept, when some slight pains caused her to open her eyes. These were slight pinchings near the surface of the skin; she thought at first that an insect had pricked the abdomen, about the navel; afterwards, these prickings having ceased, she thought no more about it. But suddenly, in about a half an hour, during a troubled sleep, a dull, gripping pain awoke her anew. This time she became angry. Was she going to have the colic? She would be very fresh, next morning, if she had to run to the pot all night! The idea of a disturbance of the bowels had been in her mind all the evening; she had felt a sense of weight, and anticipated a discharge (*débâcle*). However, she wished to restrain it, rubbed her belly, and believed she had quieted the pain. In a quarter of an hour the pain returned more violently.

"Cré, nom d'un chien," said she in a low tone, concluding to get up this time.

"In the darkness she drew out her pot, squatted upon it, and exhausted herself in fruitless efforts. The chamber was cold, and she shivered. In about ten minutes, as the colic had subsided, she returned to bed. But ten minutes later the colic commenced again. She arose, made another fruitless effort, and went to bed chilled through, where she again enjoyed a little repose. Afterward she was gripped with such force that she made a smothered plaint. Now the pains persisted, were almost continuous, with ruder shocks, as if a brutal hand had squeezed some part in the belly; and she understood it, and tremblingly stammered, under the coverlet, 'My God! my God! then it is here!'

"An agony seized upon her, a necessity for walking. She could no longer remain in bed, relighted the candle, and walked about her chamber; her tongue became parched, a burning thirst tormented her, whilst the red spots burned her cheeks. When a contraction bent her brusquely, she supported herself against the wall, seizing the wooden furniture. And hours passed in this cruel condition, without her daring even to cover her feet for fear of making a noise, protected from the cold solely by an old shawl thrown over her shoulders. Two o'clock struck, then three o'clock.

<sup>1</sup> The College Story. Valedictory Address by the Dean, Rachel L. Bodley, M. D., March 17, 1881.

<sup>2</sup> The Practice of Medicine by Women in the United States. By Drs. Emily F. Pope, Emma L. Calt, and C. Augusta Top. Read before the American Social Science Association, September 7, 1881.

"'There is no good God!' she said in a low tone, as if she must speak out. 'It is too long; it will never come to an end.'

"However, the work of preparation advanced, the sense of weight descended into the buttocks and thighs. Even when her belly allowed of a little respite, she suffered a fixed and obstinate pain there without intermission. To relieve herself, she seized her buttocks with both hands, supporting them, while she continued to walk with a hobbling gait, the legs naked, being only covered to the knees by her large stockings. No, there was no good God! Her devotion revolted; her resignation as a beast of burden, which made her accept her pregnancy as one burden more, finished by breaking down. It was not sufficient not to be able to have enough to eat to satisfy her hunger, to be the awkward and dirty scullion wench upon whom the whole house trampled; it was necessary that the masters get her with child! Ah! les salauds! She could not say whether it was the young one or the old one, for the old one had again overcome her after mardigras. . . . 'My God! I shall die!'

"And with her two contracted hands she squeezed the buttocks the more, her poor, pitiful buttocks, restrained her cries, hobbling always in her painful ugliness. About her no one stirred, they snored; she heard the sonorous drone of Julie, while with Lisa there was a whistling like the shrill music of the fife.

"Four o'clock sounded, when suddenly she believed her belly would burst open. In the midst of a pain something ruptured, water flowed out, and her stockings were soaked. She remained for a moment motionless, terrified, and stupefied, with the idea that she was draining herself in that way. Perhaps she had never been pregnant, and in the fear of some other disease, she looked at herself; she wished to see if all the blood in her body was not flowing from her. But she felt relieved; she sat for a time upon a trunk. The dirty chamber annoyed her, the candle was dying out. Then, as she could no longer walk, and as she felt the end was coming, she still had the force to spread an old oil-cloth on the bed, which Madame Jossereau had given her to put before her toilet table. She had hardly got back to bed when the labor of expulsion commenced.

"Then, during nearly an hour and a half, the violence of the pains increased without cessation. The internal contractions having ceased, it was she herself now who exerted all the muscles of her belly and loins, under the necessity of relieving herself from the intolerable weight which pressed upon her flesh. Twice she was deluded into getting up and seeking the pot with a hand fumbling with feverishness. At each new effort a trembling shook her, her face became burning, her neck was bathed with sweat, whilst she bit the bedclothes to smother her plaint, the tear, terrible and involuntary of the wood-cutter when he cleaves an oak. When the effort was over, she stammered out, as if speaking to some one, —

"'It is not possible . . . it will not come out . . . it is too large.'

"The throat thrown back, the legs wide apart, she clung with her two hands to the iron bedstead, which she shook by her convulsive efforts. It was, fortunately, a perfect head presentation (*des couches supérieures*). At times the head which presented seemed to recede, repulsed by the elasticity of the tissues, stretching almost to rupture, and atrocious cramps

seized them at each recurrence of labor pains, the great pains binding them as with an iron ring. At last the bones cracked, everything seemed to be broken, she had the frightful sensation of being split before and behind, making but one opening through which her life passed out, and the child rolled on to the bed, between her thighs, in the midst of a pool of excrement and bloody slime.

"She had given vent to a great cry, the furious and triumphant cry of mothers. Presently there were movements in the neighboring chambers, and sleepy voices saying, What was that! Is somebody being forced! Dont dream so loud! Becoming alarmed she stuffed the bedclothes again in her mouth, and by squeezing her legs, heaped the clothes over the child, which cried like a kitten. But she soon heard Julie again snoring, after turning over; whilst Lisa, again asleep, did not even whistle. Then for a quarter of an hour she enjoyed an immense relief, an infinite sweetness of calm and repose. She lay as if dead.

"Then, the colics returned. A fear aroused her; was she going to have a second! The worst of it was that when she opened her eyes she found herself in perfect darkness. Not even a candle end! and to be there all alone, in a puddle, with a viscid something between her thighs that she did not know what to do with! There were doctors for dogs, but none for her. Die, then, you and your little one! She recollected having once assisted Madame Pichon when she was confined. She must take some precautions for fear of perishing! In the meantime the child no longer cried. She put out her hand, sought for it, and felt a gut (*boyau*) coming out of the belly; and the idea came to her that she had seen this tied and cut. Her eyes had become more accustomed to the darkness; the moon which was rising vaguely lighted the chamber. Then, partly by groping and partly by instinct, she performed, without getting up, a long and painful duty. Unhooking an apron from behind her head, she broke the string, tied the gut, and cut it with the scissors taken from the pocket of her petticoat. She was in a perspiration; she laid down again. The poor little one she certainly had no desire to kill it.

"But the colic continued, very much as if there was still something there which the contractions were influencing. She pulled on the gut, at first gently, then quite strongly. Something became detached, and a mass fell out, which she removed and put in the pot. This time, thank God! it was all over, she no longer suffered. Only some warm blood ran down her legs.

"She slept for more than an hour. Six o'clock struck, when she awoke to a consciousness of her condition. Time pressed, she got up with difficulty to put things in order. A cold moon lighted up fully the chamber. After dressing, she enveloped the child in some old linen, and then wrapped it up in two newspapers. It no longer cried, but its little heart was still beating. As she had forgotten to ascertain if it was a boy or a girl, she opened the papers again. It was a girl. One more unfortunate! food for some coachman or valet, like that Louise, found on a doorstep! Not a servant was moving, and she was able to go out, leave her package in the passage Choiseul, and return quietly. She met with no one. For once in her life fortune favored her.

"Then she put her chamber in order. She rolled up the oilcloth and put it under the bed, emptied the pot, and sponged the floor. After which she stretched her-

self out in bed, with her waxy pallor, and the blood still running down between her thighs, having tamponed herself with a napkin. It was in this condition that Madame Jossereau found her at nine o'clock ;

being surprised at her non-appearance she came up to look after her. The servant complained that she was completely exhausted from the effects of a terrible diarrhoea which had disturbed her all night." W. L.

## REPORTED MORTALITY FOR THE WEEK ENDING MAY 27, 1882.

#### AUGUSTUS MASON, M. D.

AUGUSTUS MASON, M. D., died at his residence in Brighton, May 24th. He was born in Waltham, Mass., October 21, 1822, was graduated from Brown University in the class of 1841, studied medicine at Harvard University, taking his degree in 1844. He continued his medical studies in Paris until 1847, when he commenced the practice of his profession in Lowell, and removed to Brighton about 1855. He was eminently successful in his calling, holding for many years a leading position as a practitioner in this large suburban town. He was commissioned as assistant surgeon of the Forty-Third Regiment Massachusetts Volunteers, and was stationed in Newbern, N. C., where he served until the spring of 1865, when, on account of the illness of Mrs. Mason, he resigned his commission and returned home. In 1873 he relinquished his practice and went to Santa Barbara, Cal., for the benefit of his invalid wife. Here he remained till 1877, when he returned to Brighton and resumed his work. He was a member of the American Medical Association and of a number of the local societies. He was a delegate to the International Medical Congress held in London last year. He frequently contributed to the literature of his profession, and is best known for his studies upon the climatology of Southern California.

He was esteemed and beloved in Brighton, not only for his ability, but as a public-spirited citizen, prompt in the furtherance of every local interest, and was exceeded by few in the real service rendered his town. He was active in the redemption of Brighton from the long-continued detriment sustained on account of the many private slaughtering houses, and in the establishment of the abattoir, which at once added to the intrinsic value of property. Thus was removed an important cause of an ever-widening contamination of air, water, and soil. He held large properties which he had done much to develop, and, at the time of his death, was actively engaged in plans for furnishing better metropolitan steam-railroad facilities. He had been sick but a few days, and his death was sudden and unexpected.

CENSORS' MEETING.—The censors of the Suffolk District Medical Society will meet for the examination of candidates at 19 Boylston Place on Thursday, June 8th, at three o'clock.

H. C. HAVES, Secretary.

PROGRAMME OF THE EXERCISES AT THE FOURTH ANNUAL CONGRESS OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION, to be held in the hall of the Medical Library Association, 19 Boylston Place, Boston, June 12, 13, and 14, 1882. The

profession is cordially invited to attend the sessions of the congress.

June 12th. Morning session at ten o'clock. Roll-call. Reception of guests, etc. Address of Welcome, by S. W. Langmaid, M. D., chairman of committee of arrangements. President's Address. PAPERS: (1.) On Paralysis of the Laryngeal Muscles, by Louis Elsberg, M. D., New York. (2.) Laryngeal Asthma, by William C. Glasgow, M. D., St. Louis. Appointment of the nominating and auditing committees. Election of Fellows. Adjournment at one p. m. Afternoon session at three o'clock. (3.) On the Question of Hypertrophy of the Osseous Structure of the Turbinate Bones. Practically considered by D. Bryon Delavan, M. D., New York. (4.) Catarrh involving the Antrum of Highmore and its Treatment, by William H. Daly, M. D., Pittsburgh. Discussion, opened by Frank H. Bosworth, M. D., New York; On Ozena, its Pathology and Treatment. Adjournment at 5:30 p. m. Evening reception by the President, of the Fellows of the Association, to meet the medical faculty of Harvard University, and the physicians and surgeons of the Massachusetts General and City Hospitals, at his residence, 131 Boylston Street, at nine o'clock.

June 13th. Morning session at ten o'clock. Business meeting. I. Report of Secretary. II. Report of Treasurer. III. Report of Librarian. IV. Report of nominating committee. V. Reports of other committees. VI. Miscellaneous business. PAPERS, at eleven o'clock: (5.) Deformation of the Septum Narium, by E. Fletcher Ingals, M. D., Chicago. (6.) A new Operation for the Removal of the Deviated Septum in Nasal Catarrh, by William C. Jarvis, M. D., New York. (7.) Lupoid Ulceration of the Nasal Septum, by E. L. Shurley, M. D., Detroit. Adjournment at one p. m. Afternoon session at three o'clock. (8.) Impaired Cardiac Power as an Efficient Cause of Congestive Affections of the Throat, by Beverley Robinson, M. D., New York. (9.) Pharyngeal Irritation, by Harrison Allen, M. D., Philadelphia. (10.) A case of Aphonia Spastica, by Frederick I. Knight, M. D., Boston. Discussion, opened by Carl Seiler, M. D., Philadelphia: On the Nature and Forms of Laryngeal Ulcer, specially the so-called Catarrhal Ulcer. Adjournment at 5:30 p. m. Evening. Annual dinner of the Association at the Parker House, at seven o'clock.

June 14th. Morning session at ten o'clock. (11.) Ossification of the Right Arytenoid Cartilage; Separation and Expulsion following Thyrotomy for the removal of a Papilloma, by Clinton Wagner, M. D., New York. Discussion opened by S. W. Langmaid, M. D., Boston. On the Singing Voice, its Physiology, Pathology, and Treatment. Discussion opened by J. O. Roe, M. D., Rochester. On the Utility or Non-Utility of Local Applications in Chronic Catarrhal Laryngitis. Ballot for officers, 1882-83, and their induction into office. Adjournment.

GEORGE M. LEFFELERS, M. D., Secretary.

### THE DISEASES AND DANGERS INCIDENT TO SCHOOL LIFE.<sup>1</sup>

CHILDHOOD is in many respects the most important as well as the most interesting period of life, whether regarded from a physical or mental standpoint. As one has well said: "To the physiologist it is especially interesting, because it is the period of physical development and greatest functional activity; to the pathologist, because in it many diseases occur which are seldom observed in other periods of life and which present peculiar features; to the physician and vital statistician, because in it there is the greatest amount of sickness and largest number of deaths;" to the general observer, because in it intelligence begins to bud and blossom, wit and wisdom to develop into sparkling brilliancy, often eclipsing that of maturer years. While the body rapidly develops at this period of life, the brain's growth is none the less active, indeed, so rapid is it, that it is estimated that by the seventh year the weight of the organ has doubled. Taking into consideration the rapidity of growth, development, and structural change going on in body and brain, one might very naturally infer that children would be specially susceptible to disturbing influences from within and without the body, and to disease consequent upon them, an inference abundantly supported by facts and statistics.

A few years ago, I had occasion to collect statistics of mortality in early life from the records in most of the principal cities of the United States, which revealed the appalling fact that fully one half of the inhabitants did not live to the close of the fifth year of life, and that a much larger per cent died prior to the age of ten years. It is apparent to every one, even the most casual observer, that great and unusual care is necessary, in order to guard against dangers to bodily health in childhood, but it does not appear to be so generally understood, that equal watch and care is demanded in protecting the youthful brain from dangers which assail it during its rapid organic development, and from diseases of the most subtle nature, of both insidious and rapid invasion, to which it is especially subject. These, and kindred facts, have stimulated me to comment upon the bearing which school life and discipline has upon the health of body and brain, with special reference to the primary and grammar schools. Children enter the primary department at about the fifth or sixth year of age, when the bodily growth is rapid, the bodily movements and exercise are generally the most active, physical development and exercise being thus physiologically adjusted as nature intended. The confinement of young children for five or six hours in school, with as complete cessation of muscular movements as discipline can well secure, is reversing the order of natural law. This, to a certain and reasonable extent, is to be expected as a matter of course, but the objection lies in the too great and prolonged restraint exercised in the primary department. To expect that a child five or six years old is to sit bolt upright in its hard, stiff, unyielding seat for three hours, with little or no freedom of motion, and in some instances with its legs hanging unable to touch or rest

upon the floor, is asking a little too much. In the morning session of three hours the restraint is relieved by a recess of a few moments, and of course, by recitations. In the afternoon session of two hours in the grammar schools, children from seven to ten sit through the entire session, without any recess at all, and recite their lessons in their seats, not even having the rest that change of position would afford in being called upon the floor in classes.

In cases where children cannot rest their feet upon the floor, such prolonged muscular restraint has, to my certain knowledge, given rise to painful cramps of the muscles and flexor tendons of the legs, and to such an extent as to cause pain for hours after the close of the school. People in mature or adult life, who are obliged to sit for two hours on cushioned seats to listen to the most eloquent sermon or entertaining lecture, often complain of their backs and limbs. Some one may possibly raise the question: "Of what importance is a little leg ache?" I answer, secure it in the same way, for yourself, and then you will know better how to regard it. The laity do not perhaps know the cause of the pain, but medical men will at once recognize the fact, that it is the pressure upon the nerves and blood vessels in the popliteal space that causes the painful sensations.

Another derangement which physicians are frequently called upon to prescribe for in school children is the disease characterized by irregular, spasmodic, and grotesque muscular movements so well known to medical men by the name of chorea, and to the laity by the title of St. Vitus's dance. While this is, as is well known, essentially a nervous affection, the muscular restraint, taxation of the brain, and general nervous irritation consequent upon study, recitations, etc., is often, I believe, a prime factor in its causation. No one will deny that the above-mentioned causes will greatly aggravate even mild cases, and are apt to develop all latent tendencies to the disease. Making young children hold their books up high in front of their eyes in one hand, all through a class exercise in reading, contributes very materially to the same disturbance. I have on several occasions been importuned by parents of children who possessed delicate physical and exquisitely sensitive nervous organizations, to intercede with the powers that be for a modification of the rules, regulations, and general discipline, so as to enable them to keep along with their studies and classes, but I never succeeded in getting much satisfaction for myself or them. The stated and stale reply has been, "If we do it for one, we shall be obliged to do it for another." The rules of school discipline seem to be as immutable as the law of the Medes and Persians, which altereth not. The law of some school authorities, theoretically and privately, if not openly and practically, would seem to be that of the survival of the fittest and toughest. If an extensive dealer in horses, oxen, or asses, had a large drove of either, how absurd it would be in him to assert that each one had the same power of endurance, could perform the same amount of labor, and tolerate the same amount of training. If he attempted to prove his assertion he would doubtless learn that some horses would heave, some oxen would loll, some asses would kick. To claim that all of any considerable number of children can alike accomplish the same object, perform the same task in a given period of time, without injury to any, is equally absurd. Some, for instance,

<sup>1</sup> Read by Dr. G. S. Stebbins of Springfield, Massachusetts, before the District Medical Society at its annual meeting, April 18, 1882.

are more delicate physically; the nervous excitability and mental capacity of some greatly differs from that of others; some learn with difficulty, others with little effort, and to insist that the former shall keep pace with the latter is to sacrifice bodily health for the sake of mental advancement.

Another matter to which I wish to refer is the improper attention to the calls of nature. That any serious neglect on the part of the scholars is voluntary it is difficult to believe; that it is compulsory at times I know to be a fact. I refer more especially to the voidance of the urine. More than once have I been asked to consult the school authorities by parents whose children have repeatedly complained that they were not allowed to absent themselves from the school-room, when the demands were so urgent as to be with difficulty restrained. This, as medical men well know, gives rise to the condition known as irritable bladder, when the urine can only be retained in small quantities, and for a little while, without great discomfort, or incontinence of urine results, a disorder known to be very frequent in childhood. It is to be hoped that the remark of one teacher (if true), "that if the boys wanted to go out they might, but she should go with them," would in no instance hinder them in the least degree in the performance of that function in case she should ever accompany them, though it would be well for teachers who might carry this threat into execution to remember that fear has the effect to temporarily disable one in the performance of this duty, as well as to increase the frequency and force of the desire when the fear is excessive, or sufficient to cause much nervous excitement. This matter, I am ready to confess, is a troublesome one for teachers, but it is better that ninety and nine should secure an extra airing, than that one should suffer from long-continued organic disease through forced neglect. I desire to offer a protest, which, perhaps, may be best introduced here, in connection with the foregoing statements, against the occasional practice in stormy weather of keeping children of the youngest grade in continuous session from nine A. M. till one P. M., then omitting the afternoon session, so that the scholars may not have to return to school in the storm. I believe it to be true that the extra hour added to the morning session is productive of infinitely more harm than good, and that the great majority of parents would much prefer that that extra hour should be lost altogether than to have it annexed to the three hours' session of the morning. It is asking too much of such little ones to sit and study four hours. It is safe to say that they will never be much wiser for what they will learn, and the infirmities heretofore alluded to would only be aggravated.

The impairment of vision is another danger that school-children are very liable to, so much so, that it has attracted the attention of the most noted specialists of the age, who have written extensively upon the subject, and whose views you have all been made more or less familiar with in the current medical literature of the day. The more you think of the long-continued and close fixation of the eyes upon the printed page, often in an unfavorable light, and at improper distances, does it not appear less strange to you that the diseased condition of the eye known as myopia is so very prevalent? Wells, in his treatise upon diseases of the eye, says, "The seeds of short-sightedness are frequently sown in childhood, and there can be no

doubt that the degree of myopia is often greatly increased during childhood by long-continued study, more especially by insufficient illumination and a faulty construction of the tables or desks at which the pupils study and write." An insufficient illumination necessitates a close approximation of the object, which gives rise to straining of the accommodation, and congestion of the eyes." Dr. Cohn, of Leipzig, examined the eyes of 10,000 school-children, and found that he could distinctly trace the increase in the proportion of myopia according to the construction of the desks (especially the distance of the seats from the desks), and the lighting of the school-rooms. Taking the above into consideration, the absurdity of requiring all children to read and study with their books equi-distant from their eyes, will be perfectly apparent to all.

Another practice which is in vogue in some schools, and which, to the outsiders, has always appeared absurd, is to compel all scholars to walk around to the rear of the building, go down one flight of stairs and up another, in order to reach the first floor, instead of going into the front door where the teachers do. If it is for the purpose of using the water-closets, it is another good argument for their removal from the basement. In heaven's name have not the scholars stairs enough to climb in reaching the fourth story without first going down cellar? Every medical man knows how injurious so much stair-climbing is to young girls just merging into womanhood, and how it paves the way for serious derangements later on in life. The stair-climbing may not be the worst feature of the rule, for the pupils are often detained for some time in the damp, chilling atmosphere of the basement before they are allowed to ascend single file, with military precision, to the entrance hall above. The practice of making the pupils go down into this, not exactly valley of humiliation, but of darkness, dampness, and miasmatic atmosphere, to stay there and get chilled, as they inevitably must in cool weather, is ridiculous. To how many it may have been the "valley of the shadow of death" we doubtless shall never know, but that it may have been to some is by no means an absurd conjecture.

Mental diseases, such as are induced by over taxation of the brain, are by no means rare in schools. A business man applies to you suffering from pain, sense of fullness, and uneasiness in the head, more or less dizziness, occasional attacks of vertigo, general uneasiness, and inability to sleep or to fix his attention upon any one subject for any length of time, and you then declare that he is a victim of cerebral hyperemia, which, long continued, leads on to congestion, effusion, and eventually death, or, what is worse, a life of insanity. The same conditions and results often obtain among scholars who are obliged to tax their brains beyond their normal powers of endurance, excepting that insanity, perhaps, seldom results from over study in early life. I have in mind three school-children who died of disease of the brain from over study and worry, neither of whom were over twelve years of age. I know that the practice of frequent and written examinations is a trying ordeal for young pupils, and this system of forcing the youthful mind tells upon the nervous system, and seriously in many cases. For this reason the practice of stimulating young persons to excessive work, by offering prizes, is to be greatly deprecated.

Diseases due to imperfect ventilation and improper

sanitation are many, prominent among which are scarlet fever, measles, diphtheria, and lung diseases. The fact that the water-closets were ever placed in the school-house basements, from which the foul gases must of necessity arise to the rooms above, occupied by the pupils, proves the utter ignorance of those who had the matter in charge of the first principles of good ventilation and sanitary laws. Why the city fathers allow the water-closets to remain in the basement of any school-house to contaminate the air that five or six hundred school children are obliged to breathe, is a problem which admits of no satisfactory solution. This matter has been brought to the attention of both the school committee and the Board of Health during the past year, but without avail as yet. One of the teachers upon the first floor in one of the grammar schools told me that she noticed the odor from the water-closets below very perceptibly all through the warm weather. How many of the fathers of our school-children would tolerate such a state of things in their own houses? Yet hundreds of children are compelled to breathe for months pestilential odors that are infinitely more dangerous to health than half the nuisances brought to the notice of our local Board of Health.

Just here it might be well to allude to another item in which strange negligence exists. I have reference to the absence of fire escapes for the four-story school buildings, in which the only avenue of escape from the upper stories is down the main stairway, which would serve as a flue, with a strong upward draught, in case of fire. The building commissioner is instructed, I believe, to see that business and tenement blocks shall be properly furnished with fire escapes, if, indeed, there be not a law compelling him to, but I have seen no indication of any intention to provide school-houses with these means of safety and protection. A fire, as I am informed, did get quite a little start in one of the closets in the hallway of one of the grammar schools, which was discovered in its incipient stage, and hence was readily extinguished. Should a fire once get fairly started it would be next to impossible to save those in the upper stories. It certainly would seem as though the demand for fire escapes for school-houses was fully as great and urgent as for business and tenement blocks, if protection for human life is the primary object sought, as I understand it to be.

I have thus briefly called attention to several diseases and dangers attendant upon school life. I desire to put on record the statement that I do not hold the teachers responsible altogether for the matters under discussion, for I do not regard them as the authors of the rules and regulations by which the schools are governed. I believe that in the main they strive to do their duty conscientiously and well. Where there are from fifty to one hundred pupils in one room, under one teacher, she must deal with them collectively, as she has not the time to ferret out all individual peculiarities and claims. The fault lies more with the system than with the individual teacher.

The importance of improving the health and general physical welfare of the attendants upon the public schools cannot be over estimated.

Especially should ventilation and sanitation be thoroughly looked after by some one having sufficient knowledge to enable him to secure them, and determination to maintain them. Therefore I believe that there should be a medical inspector of schools appointed, whose duty should be to thoroughly examine

every school-house as often as once a month, for the purpose of obtaining exact information regarding their ventilation and general sanitary condition, and such officer should have the requisite authority to order any and every nuisance abated at once, and to enforce all needed sanitary regulations. To such an officer all cases of outbreaks of contagious and infectious diseases, as scarlet fever, measles, diphtheria, etc., might be referred, so that he could at once institute measures to prevent their spread. A rigid quarantine of all pupils afflicted with contagious diseases is as necessary as that a ship, trying to enter the port of Boston, New York, New Orleans, or any sea-port with cases of cholera, yellow fever, or small-pox on board, should be detained in strict quarantine until all danger is past. So, also, might be referred to this officer all parents who seek for any modifications of the rules of discipline in favor of their children on account of bodily weakness or mental infirmity, when he could investigate such cases, and report accordingly. Cases of pupils whose parents oppose vaccination on account of some real or fancied danger to bodily health, might, with great propriety, be left for the medical inspector to investigate and decide upon. Such an office as this, filled by a man who was clothed with the needful authority and power, and who would thoroughly, conscientiously, and fearlessly discharge his duty, would be of vastly more importance than that of janitor, school-house agent, not to say superintendent of schools.

#### HODGKIN'S DISEASE OR SCROFULA.<sup>1</sup>

BY G. LIEHMANN, M. D.

THE following case came under my observation and professional care just one year ago.

On the 14th of April, 1881, living at Baltimore at the time, I was called to Boston to treat, in consultation with Dr. Sinclair, a young married lady, twenty-eight years old, who had been seen besides by Drs. Bowditch, Ellis, and Fitz. Upon my arrival, on April 16th, I elicited the following history:—

Patient had been married some seven years and six months, mother of three fine healthy children, had pneumonia when a child of tender age, but enjoyed tolerably good health up to her marriage and showed no constitutional taint with the exception of one or two enlarged glands in the right subclavian triangle when about seventeen years old. The three pregnancies brought great gastric trouble, nausea, and vomiting up to the close of the respective terms; nutrition suffered to a great extent; first and third parturition comparatively easy, second tedious, and had to be accomplished with forceps. The mother of the patient belongs to a rachitic family, she and several other members being affected with scoliosis and kyphosis; the father was a healthy robust man without any taint. The four or five years preceding the last and fatal disease patient was in poor health, suffered from dyspepsia, from repeated attacks of gastralgia, lost flesh, but was full of energy and sprightly when not in pain.

She took pepsin, bismuth, and soda, also cod liver oil, and improved under it; she also took iodide of potassium, which did not agree with her. In Novem-

<sup>1</sup> Read before the Suffolk District Medical Society, April 29, 1882.

ber, 1880, she spent a few weeks in Baltimore, Maryland, where she met with very inclement weather, also some days in New York, where the weather was colder still, and she came home to Boston with a troublesome cough and a menstruation nearing a menorrhagia. When in Baltimore she had already consulted Doctor Arnold on account of a string of glands on the right side of the neck. As mentioned above, the iodide which the doctor prescribed our patient had to abandon on account of its physiological effects. These glands disappeared though afterwards almost entirely, and were on the day when I came to Boston not larger than the size of a pea. From February, 1881, on, the strength of our patient failed more and more, emaciation increased, a cough set in whose paroxysms ended with the expectoration of a whitish froth. The glands on the left side of the neck enlarged now; tumors in both mammae made their appearance; appetite failed, nausea and vomiting were intolerable, sleep failed, and no anodyne seemed to do any good; pulse became frequent and feeble, there was dyspnea and increasing adynamia. Dr. Bowditch, who saw the patient with Dr. Sinclair, on examination found some difference in respiration in the two lungs, and signs of an effusion in the left pleuritic cavity. Drs. Ellis, Fitz, and Sinclair found the same condition of things, and made the diagnosis of lymphadenoma with effusion. As I ascertained, the blood had been examined by them, and showed no increase of white corpuscles.

April 16th. *Status præsens.* I found patient lying on her left side, her only possible position, gasping for breath; respiration 40, speech impeded, pulse 120, small and feeble, temperature  $101.5^{\circ}$  F.; mind clear, panniculus adiposus reduced to a minimum, face distorted, anæmic. A conspicuous tumor, the size of a hen's egg, exists on the left side of neck, along the upper third of the inner edge of sterno-mastoid muscle and partially riding upon the muscle, consisting of three distinct glandular enlargements, hard, painless to the touch, and slightly movable; no swelling of the submaxillary glands; a string of enlarged glands was visible along the spine of left scapula, the largest being of the size of an almond, the smallest of a hazel nut. The axillary glands on both sides were swollen to a moderate extent, but the right thoracic glands formed again a string of tumors of more considerable magnitude, the one nearest the mamma being the largest, also hard, little, if at all, movable. There was also a bunch of glands on the posterior aspect of the neck, near the middle line, which were of rather small size. I noted hard masses, about three in number, in either mamma with infiltrations in the adjoining tissue, and the cutaneous veins over both mammae were enlarged.

The parotid, the submaxillary, inguinal, and popliteal glands were not affected. There was, however, a hardness of the entire right half of the abdomen, commencing on the left edge of right rectus muscle, occupying the right hypogastrium extending upwards to the lower edge of the liver, but not involving the latter, sensitive on deep pressure, and imparting to the palpating hands not the sensation of a peritoneal exudation, but of a tumor that could be grasped between the hands. These tumors are to be put down as retroperitoneal glands. Under the left costal arch there was to be felt a tumor of softer consistency and movable, but the most dependent segment of it could be made out, and this would recede most of the time on deep pressure. Whether this tumor was

a gland or the spleen was not to be determined with accuracy.

*Thorax.* The whole left half of thorax from the base of the lung up to the apex presented on auscultation entire absence of respiratory sounds and of vocal fremitus, perfect dullness on percussion, and a bulging out of the ribs posteriorly upon an area of the size of half a hand. The heart was dislocated to the right. The right side of the chest offered, with the exception of increased bronchial breathing, nothing abnormal.

The treatment at the time of my arrival consisted of the administration of Fowler's solution, which, however, was left off on account of the irritability of the stomach. Dr. Bowditch was again called in, and having convinced himself of the magnitude and rapid increase of the effusion, agreed with Dr. Sinclair and myself upon puncture of the pleuritic cavity. On April 20th this was done by Dr. Bowditch with his instrument, posteriorly, between the seventh and eighth ribs, and about three pints of straw-colored serum withdrawn. The heart's beat could be heard at once at its normal seat after the operation, also the respiratory murmur anteriorly and posteriorly from the apex of the lung down to the place of puncture, but below the latter there remained absolute dullness. There was, on the whole, no improvement in the subjective condition of the patient, and the following night brought the customary symptoms as nausea, vomiting, cough, and asthenia. Five days after this first tapping, which was done by Dr. Bowditch, I withdrew, in the presence of that gentleman and Dr. Sinclair, three and a half pints of serum, with no better results; eight or nine days afterwards I withdrew again about four pints, so that in all ten pints were taken from the chest. This time the chest did not fill again from the lower angle of the scapula upwards, but below it clear, sonorous resonance and distinct respiratory murmur never recurred up to the time of death. But there was and remained decided improvement in the physical signs anteriorly. The lung was apparently near the thoracic wall and had expanded, as there was a distinct sonorous and even tympanic sound on percussion and vesicular murmur. The impulse of the heart remained on the left side up to the last.

#### PROGRESS OF THE CASE.

In spite of this improvement in the chest the urgency of the subjective symptoms increased in progressive proportion. Sleeplessness was at first combated by the administration of chloral (thirty to forty grains at night), but the nausea and meteorism increased, the paroxysms of cough and expectoration, the attacks of syncope and collapse made it obvious to our minds that something new had to be done, to avert the very worst. Doses of bromide of potassium brought no relief either, and so the hypodermic injection of sulphate of morphia was decided upon. The first dose was a quarter of a grain of Magendie's solution. This brought instantaneous relief. All the above symptoms vanished. The skin, that had been icy cold and clammy, became warm, and a welcome sleep ensued after two or three hours of the most pleasant sensations. This sleep lasted twelve hours, with few interruptions, and even after awakening our patient remained comfortable for seven more hours. The most remarkable effect of the subcutaneous injection was the rally of the digestive powers of the stomach. Hungry our patient always

was, but to satisfy that desire meant inexpressible agony. Now her stomach would tolerate the heaviest food, chicken, steak, fried frog, vegetables, etc. But nineteen hours having elapsed since the first injection, the relentless enemy came on again with renewed energy and brought agony to the poor young patient and chagrin and dismay to her friends. Suffice it to say, that in spite of our reluctance, we had to keep up the hypodermic medication, the painless intervals becoming shorter, and the chances of recovery for our patient impossible. Quite against expectation the doses of the drug when increased brought not proportionally longer rest or sleep, but on the contrary produced more nausea and suffering. The best dose was from three to four drops injected every four hours. When life would seem to ebb away, when the surface of the body was icy cold, when lips and face and hands were livid, those few drops, would, as it were, infuse new life into the dying woman, revive the pulse, bring warmth to the cold surface and comfort to a human being that half a minute ago was apparently on the brink of death. This was the course of the dreadful disease up to June 23d. From that day on the middle and lower lobe of the right lung showed signs of pneumonia (dullness and crepitus). The bulging of the ribs posteriorly on the left side was still conspicuous, but the area involving it more sonorous, corresponding to the posterior axillary line; a bunch of enlarged glands on the left scapula below the spine became more distinct, of the size of a duck's egg, two of smaller size and elastic. The fever since April 16th up to date had always been moderate, the temperature ranging between 99.8° F. and 102.5° F., with intervals of apyrexia of sometimes a day or a day and a half. As a new symptom, occurring on June 29th, might be mentioned a white, doughy swelling of the right arm and hand, painless, pitting on pressure, the limb resembling milk leg. The radial pulse on the corresponding side being equal in force to that of left side, thrombosis of the artery had to be excluded, and venous thrombosis had to be diagnosed. There was no doubt compression of the right axillary vein by an enlarged gland. This swelling never went down again. Pulse 120, respiration 22. One of the enlarged left axillary glands now commenced to suppurate; but the abscess did not involve the base of the gland. Spontaneous evacuation of thick grumous pus, the discharge becoming more and more thin and offensive.

A larger thoracic gland, situated in the right anterior axillary line one and a half inches distant from the mamma, now became painful and in a few days fluctuating. This abscess involved the whole gland from the surface to the base. Great restlessness; temperature 103° F.; mental disturbance, delirium, hallucinations. Poultices of corium maculatum and flaxseed to the abscess.

June 27th. Pulse feeble; temperature 99.5 F.; mind confused, meteorism. General outlook alarming. Abscess very painful.

June 28th. Same condition. Pulse 136. Livid lips and extremities. Right arm enormously swollen.

July 1st. Pulse threadlike; jactitation. Abscess very red, shining. Incision. Discharge of pus and blood; pus not as grumous as that of first gland.

July 2d. Had a better night. Improvement of pulse in tone; mind clear; no other improvement except better rest.

July 4th. Had a fair night. Signs of effusion

also in right pleuritic cavity. Dyspnoea great. Patient occupies the sitting position with head hanging forward and over. Cyanosis increased.

July 5th. Increasing prostration. Dyspnoea less. The two abscesses still discharge. Integument over the tumor in right mamma discolored; tenderness on pressure over the spot.

July 8th. Hypodermic administration of iodide of potassium with Magendie's solution.

July 9th and 10th. The only apparent effect of it, is increased diuresis; prostration very great; pulse 130; some ascites; oedema of feet.

July 14th. The iodide of potassium injections discontinued on account of increased prostration of patient.

July 16th. Death. No autopsy allowed.

#### DIAGNOSIS AND REMARKS.

What should we call the disease whose history we gave above in the absence of an autopsy?

There are but three diseases which, in the light of the symptoms, come in for a share of consideration: (1.) Leucocythemia (glandular and splenic). (2.) Lymphadenoma (Hodgkin's disease). (3.) Scrofulous glandular disease.

*Leucocythemia* has to be excluded for the following reasons: there was no excessive (relative) production of leucocytes, which is the chief element of the disease; the blood, when examined, had not the characteristic appearance of leucæmia, that is, a pale, pus-like color but, on the contrary, was red and natural looking; furthermore, the anæmia came on *after* the development of the glandular tumors, whereas in leucæmia it precedes the glandular enlargement.

*Lymphadenoma*. Although I was and am still inclined to diagnose the case as one of scrofula, I must admit that the symptoms point forcibly to lymphadenoma. The number of the glands enlarged, the pleuritic effusion, the anæmia in the wake of the development of the tumors, the symptoms of pressure, speak forcibly for Hodgkin's disease. Furthermore, it is held by Bartholow that those very symptoms of pressure of viscera and of large vessels are absent in scrofula. How far this is correct we shall examine further on. There is, however, one negative *pathognomonic* feature dwelt upon by modern writers, and especially by Gowers, as characteristic of lymphadenoma, which was not present in our case, and that is the disinclination of the enlarged glands to suppurate. In fact the enlarged glands never suppurate in lymphadenoma. They may become larger and smaller, they may become hard when soft at first, and *vice versa*, but they do not break down. Now, in our case, two of the glands formed abscesses, giving outlet to a thick, grumous pus, intermixed with curd-like flakes. The abscesses never healed, and, in all probability, had the patient lived longer, there would have formed another abscess in one of the tumors of the right mamma, for discoloration of the skin and softening of the mass, accompanied with tenderness, commenced soon after incision of the second glandular abscess. Now, in the light of this, is not the doubt justifiable whether our case was one of lymphadenoma? and whether there was not another malady than lymphadenoma running its course under the disguise of it? and if it was not a case of lymphadenoma, what was it?

If leucæmia and Hodgkin's disease have to be excluded, the case was one of scrofulous glandular dis-

case. Although, as I mentioned before, some authors hold that there is neither anemia nor pressure symptoms, nor such a general extent of enlarged glands in scrofula, there is a case on record; I mean the celebrated case of Morgagni, which is pretty well authenticated, and which would go a great way to overthrow those statements. Morgagni describes his case as follows: The case was that of a boy, aged fifteen, who observed the enlargement of the glands of the neck three months after a severe mental shock. The glands beneath the jaw, in the neck and the thorax, were all enlarged, and tumors of the same character existed in the integuments of the abdomen and in the abdominal cavity. The progress of the disease was rapid, and accompanied with fever. After death the tumors were found full of whitish matter, fluid in some and solid in others, and some were suppurating. The whole omentum was full of strumous tubercle, and masses, from a hen's egg to that of a pigeon's in size, occupied the peritoneum, pancreas, and mesentery. There were also apparently similar growths in the fissure about each kidney. The glands in the small intestines were enlarged. One tumor, as large as a hen's egg, existed in the mediastinum, and compressed the trachea; strumous tumors were situated in the costal pleura. Hard and stony globules, the size of grains of barley, were on the surface of the lungs. Here we have numbers of enlarged glands over a large extent of the body, strumous, caseous, suppurating, intermixed with the hard, even stony, growths, as in lymphadenoma, and yet everybody who reads the above description of the case must admit the scrofulous nature of the tumors. But still there were the symptoms of visceral pressure, of rapid failure of vital force, and as great a number of enlarged glands as in true lymphadenoma. There is another case of scrofulous, glandular disease on record by Mosler. The child (of scrofulous heredity) suffered, when nine months old, from *suppurating* enlargements of cervical glands, and when two years old presented *indolent*, glandular enlargements, of the consequences of which he died later on, when five years old. There were hard growths found in the kidneys, but the spleen presented, as is sometimes the case in lymphadenoma, numbers of small, spherical, yellow nodules, such as are met with in tuberculous disease. Here the glands first affected suppurated, while those subsequently diseased presented all the characteristics of lymphadenoma. Our case belongs to the same category, and in the light of the rachitic heredity, of the suppurating of some of the glands, and, as compared with the cases of Morgagni and Mosler, must be called a *case of scrofula complicated by lymphadenoma*. Gowers speaks of cases of lymphadenoma complicated by scrofula and tuberculosis, but in these the scrofulous or tuberculous features stand in the background, whereas in *our* case, as in those of Morgagni and Mosler, the scrofulous characteristics prevail. That lymphadenoma and scrofula (respectively tuberculosis) are more intimately related to each other than is generally admitted, might be demonstrated by Mosler's case, where suppurating scrofulous glands, indolent lymphatic glands, and tuberculous growths were found in the same subject.

The investigations of Dr. Chiari as to the metamorphosis of milary tubercle throw still more light upon this subject. Chiari says: "There is a type of milary tubercle that I call the *lymphoid* tubercle, which contains mostly small, round, *lymphoid* cells, a few giant cells being interspersed."

And what do we find in lymphoma? The enlarged glands contain a great quantity of lymph corpuscles, which gradually displace the septa, and give the glands a homogeneous appearance. Thus we actually find a histologically similar condition in both diseases, which makes me think that the co-appearance of both in one subject, met with rather frequently, is more than accidental.

## REPORT REGARDING THE ADULTERATION OF FOOD AND DRUGS.

BY E. F. DAVENPORT, M. D.

THE late Legislature passed, and on May 26, 1882, the Governor approved, the following bill, which is based upon the draft for such a bill prepared by a committee of experts at the request of the National Board of Trade, and approved by that body at their convention in Washington, December 13, 1880. During 1881 very similar bills were passed in the States of New York and New Jersey.

SECT. 1 provides that no person shall manufacture or sell any drug or article of food which is adulterated within the meaning of the act.

SECT. 2. The term "drug" as used in this act shall include all medicines for internal or external use, antiseptics, disinfectants, and cosmetics. The term "food" as used herein shall include all articles used for food or drink by man.

SECT. 3. An article shall be deemed to be adulterated within the meaning of this act, —

(a.) In the case of drugs, —

(1.) If, when sold under or by a name recognized in the United States Pharmacopoeia it differs from the standard of strength, quality, or purity laid down therein;

(2.) If, when sold under or by a name not recognized in the United States Pharmacopoeia but which is found in some other pharmacopoeia, or other standard work on *materia medica*, it differs materially from the standard of strength, quality, or purity laid down in such work;

(3.) If its strength or purity falls below the professed standard under which it is sold; —

(b.) In the case of food, —

(1.) If any substance or substances have been mixed with it so as to reduce, or lower, or injuriously affect its quality or strength;

(2.) If any inferior or cheaper substance or substances have been substituted wholly or in part for it;

(3.) If any valuable constituent has been wholly or in part abstracted from it;

(4.) If it is an imitation of, or is sold under the name of, another article;

(5.) If it consists wholly or in part of a diseased, decomposed, putrid, or rotten animal or vegetable substance, whether manufactured or not; or, in the case of milk, if it is the produce of a diseased animal;

(6.) If it is colored, coated, polished, or powdered, whereby damage is concealed, or if it is made to appear better or of greater value than it really is;

(7.) If it contains any added poisonous ingredient, or any ingredient which may render it injurious to the health of a person consuming it.

The State Board of Health, Lunacy, and Charity may from time to time declare certain articles or preparations to be exempt from the provisions of this act; and the provisions hereof shall not apply to mixtures or compounds recognized as ordinary articles of food, provided that the same are not injurious to health, and are distinctly labeled as mixtures or compounds.

SECT. 4. The State Board of Health, Lunacy, and Charity shall prepare and publish from time to time lists of the articles, mixtures, or compounds declared to be exempt from the provisions of this act, in accordance with the preceding section. The said Board shall also from time to time fix the limits of variability permissible in any article of food, or any drug, or compound, the standard of which is not established by any national pharmacopoeia.

SECT. 5. The State Board of Health, Lunacy, and Charity shall take cognizance of the interests of the public health relating to the sale of drugs and food and the adulteration of the same, and shall make all necessary investigations and inquiries

in reference thereto, and for these purposes may appoint inspectors, analysts, and chemists, who shall be subject to its supervision and removal.

Within thirty days after the passage of this act the said Board shall adopt such measures as it may deem necessary to facilitate the enforcement hereof, and shall prepare rules and regulations with regard to the proper methods of collecting and examining drugs and articles of food. Said Board may expend annually an amount not exceeding three thousand dollars for the purpose of carrying out the provisions of this act.

SECT. 6. Every person offering or exposing for sale, or delivering to a purchaser, any drug or article of food included in the provisions of this act, shall furnish to any analyst or other officer or agent appointed hereunder, who shall apply to him for the purpose and shall tender him the value of the same, a sample sufficient for the purpose of the analysis of any such drug or article of food which is in his possession.

SECT. 7. Whoever hinders, obstructs, or in any way interferes with any inspector, analyst, or other officer appointed hereunder in the performance of his duty, and whoever violates any of the provisions of this act, shall be punished by a fine not exceeding fifty dollars for the first offense and not exceeding one hundred dollars for each subsequent offense.

SECT. 8. This act shall take effect at the expiration of ninety days after its passage.

The analysts appointed to examine and determine the extent of the adulteration practiced in articles of food and drugs sold in the State of New York have made their report to the State Board of Health. The samples examined were collected by two inspectors appointed by the Board, and included the principal articles of food and drug supply. Their report thereon shows that while adulteration is practiced to a greater or less extent in most of the articles examined, it is only in very few that poisonous adulteration exists. Therefore, in the matter of foods it seems to be largely a commercial question, while with drugs the adulterations without doubt seriously impair their medicinal value, thereby making it a question directly affecting the public health.

The following are abstracts from the reports of the analysts as given in the *Sanitary Engineer*: The frauds in milk differ from those of most other articles of food in that pure milk varies in composition to a very marked degree, making it impossible to establish a standard of purity except by selecting for this purpose the poorest milk produced by healthy cows. As the frauds generally consist in increasing the amount of water or diminishing the amount of fat (skimming), the chemist can only decide by his examination whether the frauds practiced have reduced the original milk below the adopted standard for the poorest milk from a healthy cow, — fat 2.5 per cent., solids, not fat, nine, water 88.5 per cent.; while a large proportion of the milk sold was found to be so moderately watered and skimmed as to be still above this standard for the poorest natural milk, much was far below this standard.

The production of oleomargarine is about equal to one fifth of the quantity of dairy butter. Butter ordinarily contains from five to ten per cent. of water, while it can be made to retain as high as fifty per cent. of water. Of the samples of butter examined some forty per cent. contained fatty matter other than genuine butter, and some ten per cent. contained an increased amount of water.

Lard cheese has to a considerable extent supplanted that made from skimmed milk and oleomargarine, which was largely manufactured some years ago.

Of sixteen samples of olive oil examined nine were considered as adulterated: one with sesame oil, four with cotton-seed oil, two with ground-nut oil, and two with either ground-nut or cotton-seed oil, or possibly with both.

Of twenty-three samples of baking soda examined only three were found adulterated, the low cost offering but little temptation. Of cream of tartar, on the other hand, out of twenty-seven samples sixteen were found adulterated, its comparatively high price offering greater inducements. Some of the samples contained not a particle of cream of tartar. The adulterants used were terra alba, starch, calcium acid phosphate, and tartaric acid. In eight samples the amount of terra alba was found to vary from three to ninety-three per cent. Five of them contained over seventy per cent.

Baking powders. These artificial substitutes for yeast consist of soda bicarbonate and either cream of tartar, tartaric acid, acid phosphate of lime, or of potash or ammonia alum. Many, moreover, contain an ammonia salt, generally the sesquibicarbonate, to prevent a natural deterioration in the powder, most contain either flour or starch. Of the eighty-four powders examined forty-nine contained cream of tartar, three tartaric acid, twenty alum, three acid phosphate of lime, eight mixtures of cream of tartar and alum, one acid phosphate and alum, seventy-three flour or starch, thirty five ammonia, and six terra alba.

All flours and meals were, as a rule, found free from adulteration.

Of twenty-three samples of arrowroot examined seventeen consisted entirely of maranta starch, while one was a mixture of maranta and tapioca, two of maranta, tapioca, and potato, and three of tapioca and potato starch.

Ten samples of wheaten bread were examined with special reference to the detection of alum, but in no case was it found.

Nine samples of pickles were examined, but no copper was found in them.

Powdered spices furnished abundant proof in support of the common reputation regarding their adulterations, for of the samples examined the following percentage of adulteration was found: In mustard sixty-six, in ginger sixty, allspice seventy, cinnamon eighty-two, cassia fifty-seven, cloves seventy-six, black pepper seventy, white pepper seventy-one, red pepper fifty, mace fifty, and in nutmeg forty per cent. of adulteration was found. The various adulterants found were integuments of grains or seeds, damaged or low-priced farinaceous substances, leguminous seeds, and various articles for bringing up the mixture as nearly as possible to the required standard of color of the genuine. Skillful roasting gives various shades of brown. A little turmeric goes a great way in imparting the rich yellow hue of real mustard to a pale counterfeit of wheat flour and terra alba, or the defective paleness of artificial black pepper is brought up to the desired tone by the judicious sifting in of a little finely pulverized charcoal. All the adulterating materials found were such as are claimed to be of themselves harmless, although a corn meal finely ground might owe all its pungency suggestive of real ginger to a judicious addition of a little salt and red pepper.

It is probably not so widely known as it should be that the demand for the materials for adulterations has called into existence a branch of manufacturing industry of no insignificant magnitude, having for its sole object the production of articles known as "spice mixtures" or "pepper dust," or, as the article is commonly designated in the technical language of the trade, "P. D." We now have as well-known articles sold by the barrel "P. D. pepper," "P. D. ginger," "P. D. cloves," and so on

through the whole spice list. When it is considered that these imitations, lacking only such flavoring with the genuine article as the dealer thinks necessary to make his goods sell, are sold at from three to four cents a pound, and the retail price paid by consumers is compared with it, the strength of the temptation to engage in such practices is clearly seen. When manufacturers openly advertise themselves as assurers and renovators of merchandise, and propose to cleanse musty and damaged beans by a new and patented process, it is full time that its significance should be considered by the public.

Of twenty-three samples of ground coffee examined nineteen contained foreign substances. These were chicory, beans, and occasionally wheat or other grain coarsely ground. One consisted entirely of roasted hominy. Three samples of coffee extract were composed chiefly of caramel and liquorice, and contained no coffee.

Of teas forty-three samples were examined, but were found to contain nothing that could be considered anything but tea.

The estimation of the quality and purity of most powdered vegetable drugs offers great difficulties, since their adulteration consists not only in the admixture of cheaper foreign material, mostly starches, flour, or cellulose, but also, and now preëminently, in the admixture of inferior brands of the same drug. Empirical and comparative tests have, therefore, more or less to be resorted to for obtaining an approximately correct and reliable estimate of their quality. Those examined were found to be to a great extent of unsatisfactory and questionable reliability.

Twenty-nine samples of quinine pills were examined, and in every case found to contain less than claimed; the two-grain pills being found to contain only from 0.9 to 1.8 grains, the three grain to contain only 1.7 to 2.8, and the five-grain pills to contain only 2.1 to 4.7 grains.

The first report under the New Jersey law has been published. The results of the examination of the market showed that about the same condition of affairs existed there as in New York. Doubtless the same will be found to be the case in Massachusetts also.

## Reports of Societies.

### PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

B. C. HAVEN, M. D., SECRETARY.

ANNUAL MEETING, April 29, 1882. Dr. J. C. WHITE in the chair: Eighty-three members present. Dr. B. JOY JEFFRIES reported

#### EIGHTY-SIX CASES OF CATARACT OPERATION

which were all done, as were those previously reported to the Society, by the modified method of Graefe. The details he omitted, as they could be read by those interested when published.

No atropine was used before the operation, and only afterwards when specially indicated. The bandage, daily removed and replaced, was kept on till the seventh or ninth day. Serrated forceps were used and held the eye by the tunic only during the transfixing of the globe. The eye was rarely touched with forceps during the rest of the operation, and then only with a

delicate iris or Passavant forceps. But one secondary operation was done, though it would have increased the vision in several other cases as well. The material was not good either in hospital or private practice. Health was *poor* in eighteen and only *fair* in twenty-one cases. The cases were not selected, and many were done with only an even chance, or less, of some vision to be gained. Ether was given in all but one case. Its routine refusal was not good practice as many cases must then be left unoperated on. There should be no hesitation in operating without ether in proper subjects. It was a serious question of shock. Two deaths after cataract operation without ether were spoken of. As has been well said, we must put this question fairly to ourselves: "Is the risk with ether greater than that from the shock of the operation itself?" He had seen the eye lost directly from not giving ether. The stimulating effect of ether has been considered of value rather than detrimental. Loss of vitreous, bleeding, etc., occur as well without as with ether. Secondary operations of course largely increase the amount of vision and so the per cent. of success; therefore records of vision before and after such operation ought to be fairly given. The advantage that a patient realizes that he can see when no ether is given is counterbalanced by the cases where he cannot, as after vitreous loss, etc., when the depressing effect will weigh against the otherwise very possible favorable result. It is not only that we Americans are more acutely sensitive to pain than the lower classes in Europe, but the *shock* is very much greater; therefore ether should not be denied in a routine way and mistaken deductions must be carefully avoided as to greater success without it, dependent as this may be on a variety of causes in addition to the secondary operations which are as requisite when ether is not given as when used.

Dr. G. LIEBMANN read a paper entitled

#### HODGKINS' DISEASE OR SCROFULA? <sup>1</sup>

Dr. R. H. FITZ said that he had been much interested in watching the progress of the case; he thought, however, that Dr. Liebmann was inclined to lay too much stress on the suppurating glands as confirming the diagnosis of scrofula, for there were none of the antecedent symptoms of inflammation which usually precede the scrofulous enlargement of lymph glands; and the suppurating took place only a short time before death.

The effect of the morphia in small doses was, as the reader had stated, most striking, and the whole progress of the case showed a great amount of nervous strength: the patient alternating between a condition apparently almost moribund, and the next day being dressed, sitting up, and playing games with some members of the household. Dr. Fitz recalled a case of a boy with Hodgkins' disease under treatment for some time at the Massachusetts General Hospital. The temperature was considerably elevated for several weeks before death, and at the autopsy a large number of acute military tubercles were found in various organs, although the lymph glands presented only the ordinary appearances of pseudo-leucemic enlargement.

Dr. KNIGHT mentioned two cases of Hodgkins' disease; one, that of a medical student; the second, that of a woman dying in Lowell. In both cases the disease ran the usual course. In the first there was a con-

<sup>1</sup> Vide page 555 of this JOURNAL.

siderable pleuritic effusion which was tapped with relief. In regard to the use of opiates, Dr. Knight emphasized the necessity of giving only a stimulant, and never a narcotic dose where there was any interference with the respiration or circulation. He believed he had seen during the last year several cases of death from such a use of morphia. He also mentioned the great value of strychnia as a respiratory stimulant.

Dr. LIEBMANN spoke of a case recently reported from Philadelphia, where a perfect cure had been effected by the use of Fowler's solution and iron internally, and hypodermic injections of Fowler's solution into the glandular enlargements.

Dr. J. B. SWIFT exhibited an

#### OBSTETRIC MANIKIN,

and explained it as follows:—

The subject of obstetrics being of such importance to the general practitioner, and the material for the practical instruction of students being so limited, it has been thought that it would be of interest to show this manikin, which serves, in a measure, to take the place of the living subject. It was designed by Drs. Budin and Pinard, of Paris, to take the place of the cadaver in demonstrating the various operations connected with obstetrics. It is a life-size model of a female figure, from the breasts to half way down the thighs, made of wood and rubber, the cavity of the pelvis being made from measurements taken from a normal pelvis. It is lined with rubber, which, extending through the pelvic cavity, represents the vagina and vulva dilated as at the termination of a labor. The abdominal walls are also constructed of rubber, and, being hollow, can be inflated with air so as to represent those of a pregnant woman, and permit of abdominal palpation. The sacrum is so arranged that it can be moved forward by a screw so as to show the most common form of pelvic deformity. The advantages claimed for the model over the cadaver are, greater neatness, the ability to demonstrate more with it, and the parts retaining their resistance after a fetus has been extracted.

I think that every one will admit its greater neatness. As to being able to demonstrate more with it, I will say that I have succeeded in demonstrating (1) a case of normal labor from the time labor begins to the expulsion of the placenta; (2) the method of diagnosis by external manipulation; (3) the various presentations and positions, and the mechanism of delivery in these; (4) manual dilatation of the cervix, and the various methods of version; (5) the application of the forceps, and the operations requiring the destruction of the child; (6) how to measure the pelvis in cases of deformity. That the parts retain their resistance is shown by the condition in which they now are after having been used for almost a year, during which time there have been at least two hundred deliveries.

The original design was merely to demonstrate abdominal palpation and instrumental deliveries, but I have added normal labor, diagnosis of presentations and positions, version, and manual dilatation of the os. In order to do this another uterus than that which came with the instrument was necessary, and I have succeeded in arranging one by which I can show the os partly dilated with membranes intact, ruptured, and os fully dilated.

As the model originally came the vaginal walls were widely dilated, and in order to make it more realistic I have arranged a vagina with the walls in apposition.

During the past winter the manikin has been used in giving instruction to students, and has been found to work with perfect satisfaction. I think it could easily be arranged for gynecological demonstrations also.

Dr. JEFFRIES showed, as some practical results of his work, the

#### RED AND GREEN STANDARD MARINE GLASS,

made by the New England Glass Works, and adopted by the United States Board of Supervising Inspectors of Steam Vessels, upon his representations, etc., to them. The lights formerly used and allowed were exhibited in contrast. He described how he tested the color and light transmitting power of the glasses, referring to a paper recently read by him before the Society of Arts of the Institute of Technology.

He also showed the first one of the color charts of Dr. Magnus and himself, as prepared by Mr. L. Prang, for this country, in the primary education in colors, and the education of the color sense. He spoke of Virchow's complaint of his medical students being unable to say which way a color shaded from lack of color education, and the need of such continued from the primary schools upwards. Dr. Jeffries explained how, by the use of this color chart, which received a diploma of merit at the International Medical Congress in Amsterdam, 1879, color-blindness could be suspected or possibly detected.

He also called attention to the law now on the Massachusetts Statute Book, which he had succeeded in having put there, and prevented the removal of this past winter. It was, however, but a "recognition of the rights of the community," who would, of course, finally insist upon what was fair to themselves, the employees, and the stockholders. The bill in Congress for an international commission, so strongly recommended by the London Medical Congress of 1881, was referred to as another very practical result of the speaker's endeavors for the control of defective vision on land and sea.

The report of the committee on social meetings, showing a balance of \$265.17, was presented and accepted.

The treasurer's report, showing a balance of \$238.22, and recommending an assessment of one dollar to meet the expenses of the coming year, was presented, audited, and accepted.

The election of officers followed, with the result as given in the JOURNAL of May 4, 1882.

#### THE AMERICAN SURGICAL ASSOCIATION.

THE third annual session of the American Surgical Association, held at Philadelphia from May 31st to June 2d inclusive, was the most successful yet held by this organization. The hall of the College of Physicians was accepted for the meetings, its use having been tendered for the occasion. Professor Gross, president of the Association, occupied the chair, and presided over its deliberations with urbanity and dignity. He was evidently gratified by the interest shown by the members and the large attendance at this meeting, and with evident satisfaction he expressed his conviction that the American Surgical Association is no longer an experiment but an assured success. About thirty leading American surgeons were registered, and nearly as many new members were elected. The papers read were of a high order, and elicited consid-

erable discussion. Entertainments were provided in the form of evening receptions, held by Profs. D. H. Agnew and S. W. Gross, and Dr. R. J. Levis, and a daily luncheon at the residence of Professor Gross, Dr. Mears, and Professor Brinton were given during the three days' session; giving the Fellows opportunities for social intercourse, which were agreeable and highly appreciated. Much credit is due to those having the matter in charge, and a vote of thanks was offered by Professor Cabell, of Virginia, to the committee of arrangements (Drs. J. Ewing Mears, S. W. Gross, and R. J. Levis), which was passed unanimously.

#### FIRST DAY'S PROCEEDINGS.

Among those registering on the first day were the officers of the Association, Prof. S. D. Gross (president), Dr. J. R. Weist, of Indiana (secretary), Dr. J. Ewing Mears, of Philadelphia (recorder); and also among those present were Drs. William T. Briggs, Nashville, Tenn.; John H. Brinton, Philadelphia; William A. Byrd, Quincy, Ill.; Samuel T. Davis, Lancaster, Pa.; J. W. S. Gourley, New York; Samuel W. Gross, Philadelphia; Moses Gunn, Chicago, Ill.; J. C. Hutchinson, Brooklyn, N. Y.; R. A. Kinloch, Charleston, S. C.; R. J. Levis, Philadelphia; Solon Marks, Milwaukee, Wis.; Hunter McGuire, Richmond, Va.; E. M. Moore, Rochester, N. Y.; C. H. Mastin, Mobile, Ala.; Thomas G. Morton, Philadelphia; Henry F. Campbell, Georgia; R. Beverly Cole, San Francisco; John B. Roberts, Philadelphia; William H. Pancoast, Philadelphia; William S. Forbes, Philadelphia; George W. Gay, Boston, and others.

The meeting was called to order by the president, who, in his address of welcome, said:—

#### ADDRESS OF WELCOME.

The question has been asked, perhaps pertinently enough, what need is there of such an organization as this, seeing that the country is full of all sorts of medical societies? The answer is not difficult; at all events I do not find it so. We have in the United States, according to a reasonable estimate, not fewer than sixty thousand medical men. Among these are large numbers of surgeons, who, in point of culture, practical skill, and reputation as writers and teachers, would be an honor to any country, however high its standard of excellence. To unite these men into one harmonious whole for the benefit of all is one of the main objects which the founders of the American Surgical Association had in view when they met at Atlanta in May, 1879. If it be said that we are striking a blow at the American Medical Association, we deny the soft impeachment. On the contrary, we shall strengthen that body by rousing it from its Rip Van Winkle slumbers and infusing new life into it. We can hurt no society now in existence or likely to come into existence hereafter. We can only hurt ourselves if we fail to do our duty. We hope to make the American Surgical Association an altar upon which we may annually lay our contributions to surgical science, and so show to the world that we are earnest and zealous laborers in the interest of human progress and human suffering. We live in a fast age. Progress stares us everywhere in the face. The surgical profession was never so busy as it is at the present moment; never so fruitful in great and beneficent results or in bold and daring exploits. Theory has given way to fact, and nothing that cannot withstand this test is worthy of ac-

ceptance. The whole field of surgery, from the structure of a boil upon a man's face to an amputation of the hip-joint, is undergoing revision. Operative surgery challenges the respect and admiration of the world, and, if it has not attained its finality, it is as nearly perfect as we can hope to make it. Therapeutic surgery too is making rapid strides; and surgical pathology was never more zealously or more successfully cultivated. New avenues are constantly being opened, and the importance of the study of physiology, in its relations to practical surgery, is daily becoming more and more apparent. In short, in whatever direction we cast our eyes, nothing but the most substantial encouragement greets our vision and urges us on to increased exertion.

Since our last meeting death has been busy in our ranks. Some of our best and most eminent members have dropped by the wayside, in the midst of their work and in the height of their usefulness. The list comprises the distinguished names of J. C. Hughes, of Keokuk; W. Warren Green, of Portland; Hugh W. Brock, of Morgantown, West Virginia; John T. Hodgen, of St. Louis; and James R. Wood, of New York. To these may be added that of H. Lenox Hodge, who died early last summer. The death of these men, all widely known and recognized as able teachers and practitioners, is a signal loss to the profession and to the country.

#### FELLOWS ELECTED.

After a short executive session the names of the following gentlemen were announced as having been elected Fellows:—

Honorary Fellows: Willard Parker, New York; John L. Atlee, Lancaster, Pa.; William Hunt, Philadelphia; J. Marion Sims, New York.

Fellows: G. A. Peters, N. Y.; William Detmold, N. Y.; Thomas T. Sabine, N. Y.; F. S. Dennis, N. Y.; J. Collins Warren, Boston; J. L. Little, N. Y.; J. H. Billings, U. S. A.; Basil Norris, U. S. A.; Leroy McLean, Troy, N. Y.; B. B. Bonteou, Troy, N. Y.; McLean Tiffany, Baltimore; David Prince, Jacksonville, Ill.; N. Senn, Milwaukee; J. A. Conington, Indianapolis; T. G. Dunott, Harrisburg; A. Smith, Baltimore; David W. Cheever, Boston; George W. Gay, Boston; R. M. Hodges, Boston; N. A. Bozeman, N. Y.; Donald McLane, Michigan; B. A. Watson, Jersey City; W. T. Bull, N. Y.; John D. Rushmore, Brooklyn, N. Y.; A. Vandever, Albany; S. B. Ward, Albany; T. H. Squire, Elmira; W. C. B. Field, Boston; J. S. Davis, N. Y., and Dr. Hayes Agnew, William Thomson, William Forbes, C. B. Nancrede, T. B. Reed, W. G. Porter, J. W. White, D. E. F. Willard, J. B. Roberts, J. M. Barton, of Philadelphia.

After the discussion of revision of certain clauses of the constitution and the appointment of committees on nomination for offices and for the selection of time and place of the next annual meeting, a recess was taken until three o'clock in the afternoon.

#### AFTERNOON SESSION.

The afternoon session was begun by J. L. CABELL, M. D., Professor of Surgery in the University of Virginia, who read a paper on

#### SANITARY CONDITIONS IN RELATION TO THE TREATMENT OF SURGICAL OPERATIONS AND INJURIES.

The following propositions were submitted for discussion:—

(1.) Statistics show that while the mortality after certain operations, heretofore regarded as exceedingly dangerous, especially those involving abdominal section, has been greatly reduced, the death-rate of amputations and excision of joints has not diminished in an equal ratio. The progressive diminution of the mortality in the former class of operations, notably the operation of ovariectomy, is doubtless due, in some measure, to improved methods of operative procedure, which it is probable have now reached final perfection, but in a yet larger measure is attributable to more careful and systematic attention to sanitary conditions, including the employment of antiseptic precautions during and after the operation.

(2.) The continued high rate of mortality after amputations in city hospitals, whence the most trustworthy statistics have been derived, stands in singular contrast with a decided decrease of the general mortality of many of the same cities, and seems to show that "the sanitary improvement of hospitals has not kept pace with that of the towns in which they are situated." But there is an obvious source of fallacy in drawing so sweeping a conclusion from the death rate of operations in hospitals. The influences which affect the results of operations are so numerous and varied, that it would be illogical to select any one of them and attribute the results to its agency, on the arbitrary assumption that, if we compare a sufficiently large number of cases, all other influences neutralize each other. Freedom from septic diseases would be a much better test of the sanitary condition of a hospital than that derived from its mortality returns.

(3.) Why, then, has not the mortality after amputations been reduced in a somewhat correspondent ratio with the marvelous diminution of the death-rate of ovariectomy? Is a death-rate of twenty-two per cent. for all amputations above the wrist and ankle the best that can be hoped for under the most favorable circumstances? Or is this high mortality only incidental to hospitals, and a necessary result of unhealthy influences inseparable from the aggregation of numbers of sick or wounded patients? It is not easy to find a satisfactory solution of this problem by referring to the somewhat equivocal and uncertain test of mortality statistics. The various influences which favor or oppose the healthy repair of wounds should be separately considered.

(4.) The prime factor in the repair of wounds being healthy blood, the utmost attention should be paid to the due performance of all the functions connected with the blood-forming and blood-purifying processes. Illustrative examples cited.

(5.) The results of operations are influenced by peculiarities of each patient's constitution, mental and physical, and by the hygienic conditions existing before, during, and after the operation.

(6.) Shock, one of the most common causes of death after primary amputations for injury, owes its malignant potency in such cases to the fact that the system has not fully recovered from the previous shock of the injury. The desideratum is to prolong the duration of the primary or apyretic period, so as to secure a complete subsidence of the original shock before operating. It is probable that this may be effected by carbolizing the injured tissues according to the method of Stephen Smith, which appears to prevent inflammation, and thus to retard, or even abolish, the "intermediary" period of wounds.

(7.) Septic complications have heretofore been the most fruitful causes of mortality after operations in hospitals, where their malignant effects are observed after secondary as well as after primary amputations.

(8.) Much may be done to prevent the development of septic poison by careful and minding attention to sanitary precautions, including all the details of personal and hospital hygiene.

(9.) The statistics of amputations in private practice and in cottage hospitals, in rural districts, when compared with those of city hospitals of the usual capacity, due allowance being made for various other influences that determine the results of operations, do not warrant the sweeping conclusion that large hospitals, even those constructed on the block system, with several stories, are necessarily liable to outbreaks of septic diseases, or that the mortality must necessarily be greater than in private practice, in the same localities, and among the same classes of the population.
